The information in the tab shows the index candidates. You can use the information to determine if there are any possible performance gains from adding a new index.
Unused Indexes Tab

This tab appears when there are indexes defined to satisfy a query which are not used. You can use this information to determine if there is a performance gain from dropping an index.

NOTE: the DMVs are reset when SQL Server is restarted, so you need to make sure you collected data for a long enough period of time to get good results from the query.
Recommendations

This tab shows recommendations about the query you are writing in order to improve the performance of the system. Recommendations may be:

- Misuses of DEALLOCATE
- Avoiding "Work tables" when "table variables" can be used.
- Improvements on a SQL statement to improve the performance
- ...

Error Pane

When ISQL Performance creates a new report, it includes an entry in the Error Pane to inform the user about the availability of that new report. As you can see in the next figure, the Error Pane includes a Performance tab where information about the available performance information is indicated.

The Performance tab indicator is green which is also added to the ISQL Editor gutter, indicating which SQL statements have a specific performance report.
Execution and Execution-related SQL Editor options

The ISQL Editor lets you execute all or part of your SQL scripts. Unless you are executing large scripts that have multiple statements within them, or you need to view optimizer statistics, you execute most of your SQL scripts without options.

The following topic describe the execution related options available from the SQL Editor.

- Locking a SQL Editor Window to a Datasource
- Setting up the Execution Environment with Query options
- Executing Entire Scripts in the SQL Editor
- Executing Partial Scripts in the SQL Editor
- Executing the Current Statement
- Step Executing a Script
- Using the Query Plan Facility
- Canceling a Query

See Also

- Script/File Execution Facilities.
Locking a SQL Editor Window to a Datasource

When executing scripts or setting query options, all directives are issued to the currently active datasource. Since the selected datasource can be changed, locking the SQL Editor window to a datasource ensure that all directives are issued to the correct datasource and that sessions are set up to terminate properly.

Note: For information on the ways in which the selected datasource can change, see Connected/Selected Datasource options.

A SQL Editor window’s locked/unlocked status is shown by the Lock - Unlock Connection button on the SQL Editor Toolbar. For information on the toolbar, see SQL Editor Windows Basics.

<table>
<thead>
<tr>
<th>Lock - Unlock Connection button state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Locked</td>
<td>Manual session termination. The ISQL window will open a session and keep it open while the window remains open, unless the DBMS terminates the session due to a timeout, or the session is closed. The ISQL Window does not respond to datasource change events in other windows, and only uses the current connection for subsequent execution.</td>
</tr>
<tr>
<td>Unlocked</td>
<td>Automatic session terminations. The ISQL window will execute each statement in a new session with no session state maintained between them. When explicitly unlocking an ISQL window, the connection can be returned to the connection pool or disconnected. For details, see the DBMS specific information under ISQL Options.</td>
</tr>
</tbody>
</table>

To toggle the datasource locked/unlocked status of a SQL Editor window

1. Click the Lock - Unlock Connection button.
Setting up the Execution Environment with Query options

A set of options corresponding to DBMS-specific query options are available. They let you customize the execution environment for an ISQL session with query-handling directives in areas such as performance, logging/reporting, and error handling.

See the following topics for descriptions of the options available for the DBMS you are working against:

- DB2 LUW Query options
- DB2 z/OS Query options
- MySQL Query options
- Oracle Query options
- SQL Server Query options
- Sybase ASE Query options
- Sybase IQ Query options
- Teradata Query options

If you do not change the default settings, a set of default query option settings are sent to the server, one set per DBMS platform. You can, however save a set of query option settings for each DBMS, and have that set of settings used as the default for ISQL sessions against that platform. As well, during any ISQL session, you can modify the query option settings for the current session.

The query options you select apply only to the current ISQL window instance. In addition, non-default query option settings you specify are not saved. You can however, save a set of query option settings to a file and subsequently open that file in other ISQL editor sections to have those settings applied to that session.

To specify query options:

1. With the SQL Editor open, select **Query Options** from the **Query** menu.

Once open, you have the following options:

- Set each option manually using the associated check box.

- Use the **Save** button to open a dialog that lets you save the current option query settings to an XML file. The dialog also has a **Load these query options as default** option that lets you use the settings in the saved file as the default query option settings for the current platform. Exercising this option sets the **Load Query Options** feature on the DBMS-specific **ISQL** tab of the Options editor to specify the file you saved. For more information, see **ISQL Options**.
Use the **Load** button to open a dialog that lets you locate and open a previously-saved XML file containing query option settings.

Use the **Reset** button to restore the query option defaults.

2. Click **OK** to set query options for the current ISQL window session.

**Note:** For information on conditions for which query options are sent to the server, see **Setting up the Execution Environment with Query options**.

### When query options are sent to the server

Locked connections optimize sending query options to the server. Since an unlocked connection results in a new connection for each execution, query options must be sent with each execution. The following table outlines the specific cases:

<table>
<thead>
<tr>
<th>Session</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>unlocked</strong></td>
<td>When you open an ISQL window, if you not lock the connection, all query options are sent to the server each time you execute a script, immediately before executing the actual script. As long as the connection remains unlocked, all query options are sent to the server at each execution. Similarly if you unlock a currently locked session, all query options are sent to the server at each subsequent execution. For information on locking sessions, see <a href="#">SQL Editor Toolbar Options</a>.</td>
</tr>
<tr>
<td><strong>locked</strong></td>
<td>When you open an ISQL and lock the connection, all query options are sent to the server on the first execution. On subsequent executions, if you do not modify query option settings, no query options are sent to the server on subsequent executions. If you open <strong>Query Options</strong> dialog and modify options, on the next execution only the modified settings are sent to the server. These rules apply as long as the connection remains locked.</td>
</tr>
</tbody>
</table>

### DB2 LUW Query options

The following settings are available when setting query options against a DB2 LUW datasource:
## Setting up the Execution Environment with Query options

<table>
<thead>
<tr>
<th>Query Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Batch Delimiter</strong></td>
<td>The batch separator must be a viewable character and not a space, new line, or tab. The default (semi-colon) has been selected to ensure compatibility with the features of DBArtisan and the respective platform, but can be customized. Note: A custom delimiter works only from within an ISQL window and can’t be used for extraction operations.</td>
</tr>
<tr>
<td><strong>Check syntax when executing</strong></td>
<td>TRUE/FALSE</td>
</tr>
<tr>
<td><strong>Create Explain plan tables if required</strong></td>
<td>If set to TRUE, Explain Plan tables are created, as necessary. If set to FALSE and you don’t manually create tables, Explain Plan operations will fail.</td>
</tr>
<tr>
<td><strong>Create explain plan tables on the SYSTOOLS schema</strong></td>
<td>If set to TRUE, Explain Plan tables are created on the SYSTOOLS schema. If the tables already exist in the user’s default schema, those tables will continue to be used. Refer to DB2 documentation for a listing of Explain Plan tables that must be deleted in order to use the SYSTOOLS option. If set to FALSE, Explain Plan tables are created under the user’s default schema.</td>
</tr>
<tr>
<td><strong>Max Errors Before Aborting</strong></td>
<td>Select the maximum number of errors encountered before a script is aborted. Setting this value to zero disables the feature.</td>
</tr>
<tr>
<td><strong>Row Count</strong></td>
<td>When set to TRUE, a query is terminated after returning the specified number of rows.</td>
</tr>
<tr>
<td><strong>Run Script with batch execution</strong></td>
<td>TRUE/FALSE</td>
</tr>
<tr>
<td><strong>Isolation Level</strong></td>
<td>Lets you set DB2 Isolation Levels of UNCOMMITTED READ, RESET, CURSOR STABILITY, REPEATABLE READ, or READ STABILITY.</td>
</tr>
<tr>
<td><strong>Prepare Batch</strong></td>
<td>For the current SQL Editor window, setting this check box enables bind variable parameterization. This lets you provide named and unnamed variable values as a script executes. For details, see [Bind Variable Parameterization in Prepared Statements (Dynamic SQL)](<a href="https://www.embarcadero.com/products/rad">https://www.embarcadero.com/products/rad</a> Studio/docs/17/DB2 Dynamic SQL)</td>
</tr>
</tbody>
</table>

### DB2 z/OS Query options

The following settings are available when setting query options against a DB2 z/OS datasource:
### Setting up the Execution Environment with Query options

<table>
<thead>
<tr>
<th>Query Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Batch Delimiter</strong></td>
<td>The batch separator must be a viewable character and not a space, new line, or tab. The default (semi-colon) has been selected to ensure compatibility with the features of DBArtisan and the respective platform, but can be customized. Note: A custom delimiter works only from within an ISQL window and can’t be used for extraction operations.</td>
</tr>
<tr>
<td><strong>Check syntax when executing</strong></td>
<td>TRUE/FALSE</td>
</tr>
<tr>
<td><strong>Max Errors Before Aborting</strong></td>
<td>Select the maximum number of errors encountered before a script is aborted. Setting this value to zero disables the feature.</td>
</tr>
<tr>
<td><strong>Row Count</strong></td>
<td>When set to TRUE, a query is terminated after returning the specified number of rows.</td>
</tr>
<tr>
<td><strong>Run Script with batch execution</strong></td>
<td>TRUE/FALSE</td>
</tr>
<tr>
<td><strong>Prepare Batch</strong></td>
<td>For the current SQL Editor window, setting this check box enables bind variable parameterization. This lets you provide named and unnamed variable values as a script executes. For details, see <a href="https://www.embarcadero.com/products/rad%EF%BF%BD%EF%BF%BD">Bind Variable Parameterization in Prepared Statements (Dynamic SQL)</a>.</td>
</tr>
</tbody>
</table>

### MySQL Query options

The following settings are available when setting query options against a MySQL datasource:
<table>
<thead>
<tr>
<th>Query Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Batch Delimiter</td>
<td>The batch separator must be a viewable character and not a space, new line, or tab. The default (semi-colon) has been selected to ensure compatibility with the features of DBArtisan and the respective platform, but can be customized. Note: A custom delimiter works only from within an ISQL window and can’t be used for extraction operations.</td>
</tr>
<tr>
<td>Big Tables</td>
<td>When set to TRUE, allows big result sets by saving all temporary sets to file. This can slow queries.</td>
</tr>
<tr>
<td>Client Character</td>
<td>Default character set.</td>
</tr>
<tr>
<td>Insert ID</td>
<td>Choose a value to be used a following INSERT or ALTER TABLE statement when you supply an AUTO_INCREMENT value.</td>
</tr>
<tr>
<td>Interactive Timeout</td>
<td>28800 default</td>
</tr>
<tr>
<td>Last Insert ID</td>
<td>Set the value to be stored in the binary log when you use LAST_INSERT_ID() in a statement that updates a table.</td>
</tr>
<tr>
<td>Max Errors Before Aborting</td>
<td>Select the maximum number of errors encountered before a script is aborted. Setting this value to zero disables the feature.</td>
</tr>
<tr>
<td>Query Cache Type</td>
<td>The query is cached for ON or DEMAND.</td>
</tr>
<tr>
<td>Row Count</td>
<td>When set to TRUE, a query terminates after returning the specified number of rows.</td>
</tr>
<tr>
<td>SET Other Variables</td>
<td>Variables to be set at runtime.</td>
</tr>
<tr>
<td>SQL Auto IS NULL</td>
<td>When set to TRUE, enables you to find the last inserted row for a table.</td>
</tr>
<tr>
<td>SQL Big Selects</td>
<td>When set to TRUE, SELECT statements likely to take a very long time to execute will be aborted (i.e., where the number of rows examined exceeds the max join size)</td>
</tr>
<tr>
<td>SQL Big Tables</td>
<td>TRUE/FALSE</td>
</tr>
<tr>
<td>SQL Buffer Result</td>
<td>When set to TRUE, forces results from SELECT statements into temporary tables.</td>
</tr>
<tr>
<td>SQL Log Bin</td>
<td>When set to TRUE, allows logging to the binary log.</td>
</tr>
<tr>
<td>SQL Log Off</td>
<td>When set to TRUE, no logging is done to the general query log.</td>
</tr>
</tbody>
</table>
Setting up the Execution Environment with Query options

**SQL Log Update**  
When set to TRUE, allows logging to the binary log.

**SQL Low Priority Updates**  
When set to TRUE, gives table modifying operations lower priority than SELECT operations.

**SQL Max Join Size**  
When set to TRUE, you can catch SELECT statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a WHERE clause, that take a long time, or that return millions of rows.

**SQL Quote Show Create**  
When set to TRUE, table and column names will be quoted.

**SQL Safe Updates**  
When set to TRUE, the query aborts UPDATE or DELETE statements that do not use a key in the WHERE clause or a LIMIT clause. This makes it possible to catch UPDATE or DELETE statements where keys are not used properly and that would probably change or delete a large number of rows.

**SQL Select**  
The maximum number of records that should be returned from SELECT statements.

**SQL Warnings**  
Defines whether or not single row insert statements generate an information string in the event of a warning.

**Transaction Isolation**  
Repeatable Read is the default. Read Committed, Read Uncommitted, and Serializable are the other options. Refer to MS SQL Query Options dialog box for an explanation.

**Unique Checks**  
Performs uniqueness checks for secondary indexes of MyISAM tables.

**Prepare Batch**  
For the current SQL Editor window, setting this check box enables bind variable parameterization. This lets you provide named and unnamed variable values as a script executes. For details, see [Bind Variable Parameterization in Prepared Statements (Dynamic SQL)](https://example.com).

---

**Oracle Query options**

The following settings are available when setting query options against an Oracle datasource:

<table>
<thead>
<tr>
<th>Category</th>
<th>Query Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query Analysis</td>
<td>Network Activity</td>
<td>True/False</td>
</tr>
<tr>
<td></td>
<td>Execution</td>
<td>True/False</td>
</tr>
<tr>
<td></td>
<td>Information</td>
<td></td>
</tr>
<tr>
<td></td>
<td>I/O Activity</td>
<td>True/False</td>
</tr>
<tr>
<td></td>
<td>Sort Activity</td>
<td>TRUE/FALSE</td>
</tr>
</tbody>
</table>
### Index Activity
- True/False

### Parse Activity
- TRUE/FALSE

### Table Activity
- True/False

### OS Activity
- TRUE/FALSE

### Wait Activity
- True/False

### Miscellaneous

#### Batch Delimiter
- The batch separator must be a viewable character and not a space, new line, or tab. The default ("/") has been selected to ensure compatibility with the features of DBArtisan and the respective platform, but can be customized.

- Note: A custom delimiter works only from within an ISQL window and can’t be used for extraction operations.

#### Check syntax when executing
- TRUE/FALSE

#### LONG Size Bytes
- 8,192 is the default

#### Max Errors Before Aborting
- Select the maximum number of errors encountered before a script is aborted. Setting this value to zero disables the feature.

#### Row Count
- When set to TRUE, a query terminates after returning the specified number of rows.

#### Run Script with batch execution
- TRUE/FALSE

#### Prepare Batch
- For the current SQL Editor window, setting this check box enables bind variable parameterization. This lets you provide named and unnamed variable values as a script executes. For details, see [Bind Variable Parameterization in Prepared Statements (Dynamic SQL)](#)

### SQL Server Query options

The following settings are available when setting query options against a SQL Server datasource:
### Setting up the Execution Environment with Query options

<table>
<thead>
<tr>
<th>Category</th>
<th>Query Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query Analysis</td>
<td>Show Plan</td>
<td>When set to TRUE, reports data retrieval methods chosen by the Microsoft SQL Server query optimizer.</td>
</tr>
<tr>
<td></td>
<td>No Count</td>
<td>Terminates the message indicating the number of rows affected by a Transact-SQL statement from being returned as part of the results.</td>
</tr>
<tr>
<td></td>
<td>No Exec</td>
<td>When set to TRUE, compiles each query without executing it.</td>
</tr>
<tr>
<td></td>
<td>Force Plan</td>
<td>When set to TRUE, processes a join in the same order as tables appear in the FROM clause of a SELECT statement only.</td>
</tr>
<tr>
<td>Statistics I/O</td>
<td></td>
<td>Lets you display information regarding the amount of disk activity generated by Transact-SQL statements.</td>
</tr>
<tr>
<td>Statistics Time</td>
<td></td>
<td>Displays the number of milliseconds required to parse, compile, and execute each statement.</td>
</tr>
<tr>
<td>Parse Only</td>
<td></td>
<td>When set to TRUE, checks the syntax of each Transact-SQL statement and returns any error messages without compiling or executing the statement. When TRUE, makes Microsoft SQL Server only parse the statement. When FALSE, makes Microsoft SQL Server compile and execute the statement. Do not use Parse Only in a stored procedure or a trigger.</td>
</tr>
<tr>
<td>Arithmetic</td>
<td>Ignore</td>
<td>When set to TRUE, any overflow caused by a resulting value that is larger than a column’s specified size is ignored.</td>
</tr>
<tr>
<td></td>
<td>Overflow</td>
<td>If set to TRUE, queries will be aborted on encountering a value greater than the specified size.</td>
</tr>
</tbody>
</table>
**SET Options**
The **Send Set Options** setting dictates whether the remaining ANSI SQL Options in this category are sent to the server. The default for this option is set using the **Enable SET query options** setting on the ISQL tab of the Options editor. For details, see **ISQL Options**. If the **Send Set Options setting** is enabled, the remaining settings in this category let you specify the specific ANSI SQL options that are sent to the server: **ansi_defaults**, **ansi_nulls**, **ansi_null_dflt_on**, **QUOTED IDENTIFIER**, **cursor_close_on_commit**, **ANSI_PADDING**, **ANSI_WARNINGS**, **IMPLICIT_TRANSACTIONS**, and **CONCAT_NULL_YIELDS_NULL**.
The initial default values are hard-coded, not obtained from server settings.

**Transactions**

**Isolation Level**
Read Committed: Microsoft SQL Server default transaction isolation level. Specifies that shared locks are held while data is read to avoid dirty reads. You can change the data before the end of the transaction, resulting in nonrepeatable reads or phantom data. Read Uncommitted: The lowest level of transaction isolation. Transactions are isolated to ensure that physically corrupt data is not read. Applies dirty read, or isolation level 0 locking, which ensures that no shared locks are issued and no exclusive locks are honored. If set, it is possible to read uncommitted or dirty data values in the data can be changed and rows can appear or disappear in the data set before the end of the transaction. Repeatable Read: Places locks on all data used in a query, preventing other users from updating the data. Other users can insert new phantom rows into the data and are included in later reads in the current transaction. Concurrency is lower than Read Committed. Use this option only when necessary. Serializable: The highest level of transaction isolation. Transactions are completely isolated from one another. Places a range lock on the data set, preventing other users from updating or inserting rows into the data set until the transaction is complete. Concurrency is lower than Repeatable Read. Use this option only when necessary.

**Miscellaneous**

**Batch Delimiter**
The batch separator must be a viewable character and not a space, new line, or tab. The default ("go") has been selected to ensure compatibility with the features of DBArtisan and the respective platform, but can be customized.

Note: A custom delimiter works only from within an ISQL window and can’t be used for extraction operations.

**Max Errors Before Aborting**
Select the maximum number of errors encountered before a script is aborted. Setting this value to zero disables the feature.

**Row Count**
When set to TRUE, a query terminates after returning the specified number of rows.

**Run Script with batch execution**
**TRUE/FALSE**

**Text Size**
8,192 is the default
Setting up the Execution Environment with Query options

Prepare Batch  
For the current SQL Editor window, setting this check box enables bind variable parameterization. This lets you provide named and unnamed variable values as a script executes. For details, see Bind Variable Parameterization in Prepared Statements (Dynamic SQL).

Sybase ASE Query options

The following settings are available when setting query options against a Sybase ASE datasource:

<table>
<thead>
<tr>
<th>Category</th>
<th>Query Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query Analysis</td>
<td>Show Plan</td>
<td>When set to TRUE, reports data retrieval methods chosen by the Microsoft SQL Server query optimizer.</td>
</tr>
<tr>
<td></td>
<td>No Count</td>
<td>Terminates the message indicating the number of rows affected by a Transact-SQL statement from being returned as part of the results.</td>
</tr>
<tr>
<td></td>
<td>No Exec</td>
<td>When set to TRUE, compiles each query without executing it.</td>
</tr>
<tr>
<td>Statistics I/O</td>
<td></td>
<td>Let you display information regarding the amount of disk activity generated by Transact-SQL statements.</td>
</tr>
<tr>
<td>Statistics</td>
<td>Time</td>
<td>Displays the number of milliseconds required to parse, compile, and execute each statement.</td>
</tr>
<tr>
<td>Statistics</td>
<td>Subquery Cache</td>
<td>Displays the number of cache hits, misses, and the number of rows in the subquery cache for each subquery.</td>
</tr>
<tr>
<td>Force Plan</td>
<td></td>
<td>When set to TRUE, processes a join in the same order as tables appear in the FROM clause of a SELECT statement only.</td>
</tr>
<tr>
<td>Prefetch</td>
<td></td>
<td>When set to TRUE, enables large I/Os to the data cache. When set to FALSE, disables large I/Os to the data cache.</td>
</tr>
<tr>
<td>Parse Only</td>
<td></td>
<td>When set to TRUE, checks the syntax of each Transact-SQL statement and returns any error messages without compiling or executing the statement. When TRUE, makes Microsoft SQL Server only parse the statement. When FALSE, makes Microsoft SQL Server compile and execute the statement. Do not use Parse Only in a stored procedure or a trigger.</td>
</tr>
<tr>
<td>Transactions</td>
<td>Chained</td>
<td>Invokes a begin transaction before the following statements: delete, insert, open, fetch, select, and update. You must still explicitly close the transaction with a commit.</td>
</tr>
<tr>
<td></td>
<td>Isolation Level</td>
<td>0 1: Sybase default isolation level. Prevents dirty reads. 2: Prevents dirty and non-repeatable reads. 3: Prevents dirty and non-repeatable reads and phantoms. This level is equivalent to performing all selects with holdlock.</td>
</tr>
</tbody>
</table>
### Setting up the Execution Environment with Query options

<table>
<thead>
<tr>
<th>Arithmetic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore Overflow</td>
<td>When set to TRUE, any overflow caused by a resulting value that is larger than a column’s specified size is ignored.</td>
</tr>
<tr>
<td>Abort On Overflow</td>
<td>If set to TRUE, queries will be aborted on encountering a value greater than the specified size.</td>
</tr>
<tr>
<td>Abort On Truncation</td>
<td>Specifies behavior following a loss of scale by an exact numeric datatype during an implicit datatype conversion. When set to TRUE, a statement that causes the error is aborted but other statements in the transaction or batch continue to be processed. When set to FALSE, query results are truncated processing continues.</td>

Embarcadero Technologies 1375
Setting up the Execution Environment with Query options

Text Formatting (Sybase ASE 15)

These options let you generate diagnostic output in text format, using the Sybase ASE `set option` command. To use these options, you must be using the `sa_role` or have the `set tracing` permission. You can select ON, OFF BRIEF, or LONG standard Sybase ASE settings. If you are not using the `sa_role` or do not have the `set tracing` permission, use only the DEFAULT selection for each Text Formatting Set option is available. That setting has no effect. Using other selections without the required role or permission will result in an error on the next execution. For detailed information on these options and required permissions or roles, see the Sybase documentation. For access, see Accessing Third Party Documentation. Short descriptions message content displayed for Text Formatting `set option` command options are:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show</td>
<td>A collection of details, where the collection depends on the choice of BRIEF, LONG, ON, or OFF.</td>
</tr>
<tr>
<td>Show Lop</td>

### Show Missing Stats
Details of useful statistics missing from SARG/join columns.

### Prepare Batch
For the current SQL Editor window, setting this check box enables bind variable parameterization. This lets you provide named and unnamed variable values as a script executes. For details, see Bind Variable Parameterization in Prepared Statements (Dynamic SQL).

## Sybase IQ Query options

The following settings are available when setting query options against a Sybase IQ datasource:

<table>
<thead>
<tr>
<th>Query Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Send SET Options</strong></td>
<td>The <strong>Send Set Options</strong> setting applies to all settings except those in the bottom-most <strong>Miscellaneous</strong> category. It dictates whether the child options are sent to the server. The default for this option is set using the <strong>Enable SET query option</strong> setting on the ISQL tab of the Options editor. For details, see <strong>ISQL Options</strong>.</td>
</tr>
<tr>
<td><strong>Isolation Level</strong></td>
<td>Specifies the locking isolation level for Catalog Store tables.</td>
</tr>
<tr>
<td><strong>Allow Nulls By Default</strong></td>
<td>Sets the ALLOW_NULLS_BY_DEFAULT option, controlling whether new columns created without specifying either NULL/NOT NULL are allowed to contain NULL values.</td>
</tr>
<tr>
<td><strong>ANSI Null</strong></td>
<td>Sets the ANSINULL option, controlling the interpretation of using = and != with NULL.</td>
</tr>
<tr>
<td><strong>Conversion Error</strong></td>
<td>Sets the CONVERSION_ERROR option, controlling reporting of data type conversion failures on fetching information.</td>
</tr>
<tr>
<td><strong>Divide-by-zero Error</strong></td>
<td>Sets the DIVIDE_BY_ZERO_ERROR option, controlling reporting of division by zero.</td>
</tr>
<tr>
<td><strong>SET quoted_identifier</strong></td>
<td>Sets the QUOTED_IDENTIFIER option, controlling the interpretation of strings enclosed in double quotes.</td>
</tr>
<tr>
<td><strong>SQL Flagger Error Level</strong></td>
<td>Sets the SQL_FLAGGER_ERROR_LEVEL option, controlling the behavior in response to any SQL code that is not part of the specified standard.</td>
</tr>
<tr>
<td><strong>SQL Flagger Warning Level</strong></td>
<td>Sets the SQL_FLAGGER_WARNING_LEVEL option, controlling the response to any SQL that is not part of the specified standard.</td>
</tr>
<tr>
<td><strong>String R-Truncation</strong></td>
<td>Sets the STRING_RTRUNCATION option, determining whether an error is raised when an INSERT or UPDATE truncates a CHAR or VARCHAR string.</td>
</tr>
<tr>
<td><strong>T-SQL Variables</strong></td>
<td>Sets the TSQL_VARIABLES option, controlling whether the @ sign can be used as a prefix for Embedded SQL host variable names.</td>
</tr>
<tr>
<td>Setting up the Execution Environment with Query options</td>
<td></td>
</tr>
<tr>
<td>-----------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Disable RI Check</td>
<td>Sets the DISABLE_RI_CHECK option, allowing LOAD, INSERT, UPDATE, or DELETE operations to bypass the referential integrity check to improve performance.</td>
</tr>
<tr>
<td>Early Predicate Execution</td>
<td>Sets the EARLY_PREDICATE_EXECUTION option, controlling whether simple local predicates are executed before query optimization.</td>
</tr>
<tr>
<td>Extended Join Syntax</td>
<td>Sets the EXTENDED_JOIN_SYNTAX option, controlling whether queries with an ambiguous syntax for multi-table joins are allowed or reported as an error.</td>
</tr>
<tr>
<td>Index Advisor</td>
<td>Sets the INDEX_ADVISOR option, generating messages suggesting additional column indexes that may improve performance of queries.</td>
</tr>
<tr>
<td>Index Advisor Max Rows</td>
<td>Sets the INDEX_ADVISOR_MAX_ROWS option, setting the maximum number of unique advice messages stored by the index advisor.</td>
</tr>
<tr>
<td>Infer Subquery Predicates</td>
<td>Sets the INFER_SUBQUERY_PREDICATES option, controlling the optimizer’s inference of additional subquery predicates.</td>
</tr>
<tr>
<td>Join Optimization</td>
<td>Sets the JOIN_OPTIMIZATION option, enabling or disabling the optimization of the join order.</td>
</tr>
<tr>
<td>Large Doubles Accumulator</td>
<td>Sets the LARGE.DOUBLES_ACCUMULATOR option, controlling which accumulator to use for SUM or AVG of floating-point numbers.</td>
</tr>
<tr>
<td>Minimize Storage</td>
<td>Sets the MINIMIZE_STORAGE option, minimizing use of disk space for newly created columns.</td>
</tr>
<tr>
<td>No Exec</td>
<td>Sets the NOEXEC option, generating the optimizer query plans instead of executing the plan.</td>
</tr>
<tr>
<td>Non ANSI NULL Varchar</td>
<td>Sets the NON_ANSI_NULL_VARCHAR option, controlling whether zero-length VARCHAR data is treated as NULLs for INSERT, ILOAD, and UPDATE operations.</td>
</tr>
<tr>
<td>On Charset Conversion Error</td>
<td>Sets the ON_CHARSET_CONVERSION_FAILURE option, controlling the action taken on a character conversion error.</td>
</tr>
<tr>
<td>Query Name</td>
<td>Sets the QUERY_NAME option, giving a name to an executed query in its query plan.</td>
</tr>
<tr>
<td>Query Detail</td>
<td>Sets the QUERY_DETAIL option, specifying whether additional query information is included in the Query Detail section of the query plan.</td>
</tr>
<tr>
<td>Query Plan</td>
<td>Sets the QUERY_PLAN option, specifying whether or not additional query plans are printed to the message file.</td>

</tr>
<tr>
<td>Max Errors Before Aborting</td>
<td>Lets you limit the number of errors returned before aborting a query.</td>
</tr>
<tr>
<td>Run Script With Batch Execution</td>
<td>When selected, scripts are executed statement by statement (batch delimited).</td>
</tr>
<tr>
<td>Prepare Batch</td>
<td>For the current SQL Editor window, setting this check box enables bind variable parameterization. This lets you provide named and unnamed variable values as a script executes. For details, see Bind Variable Parameterization in Prepared Statements (Dynamic SQL).</td>
</tr>
</tbody>
</table>
Executing Entire Scripts in the SQL Editor

You can execute the contents of an SQL editor window.

To execute an entire script

1. On the Query menu, select Execute.

The script starts to execute. If there are results, a Results tab opens letting you work with the results. For details, see Using the Results Editor.
Executing Partial Scripts in the SQL Editor

You can execute a selected portion of a script within an SQL editor window.

To execute a partial script

1. Ensure that partial script execution is enabled. For details, see ISQL Options - Main Tab.
2. Select the portion of the script to be executed.
3. On the Query menu, select Execute.

The selected statements execute. If there are results, a Results tab opens letting you work with the results. For details, see Using the Results Editor.
Executing the Current Statement

The **Execute Statement** command lets you execute an individual statement where statements in the script are terminated with a valid delimiter (; or /).

**Note:** The **Execute Statement** command is only available if the **Scan entire file for context** option in the Options Editor is selected. For details, see [ISQL Options - Code Assist - Advanced Tab](#).

**To execute a delimiter-terminated statement**

1. Place the cursor anywhere within the statement.
2. From the **Query** menu, select **Execute Statement**.

The statement is executed and if results are returned, the Results Editor opens. For details, see [Using the Results Editor](#).

As a visual aid, the executed statement is highlighted.

```
SELECT * FROM ADMINISTRATOR.DEPARTMENT;
SELECT * FROM ADMINISTRATOR.EMPLOYEE;
SELECT * FROM ADMINISTRATOR.CUSTOMER;
```

**Topics**

- Execution and Execution-related SQL Editor options.
Step Executing a Script

Step execution of scripts is an invaluable method to debug your scripts. The Step Execution facility lets you step through each batch in your script. While some batches can include many lines of code, some batches can consist of one line. The Step Execution facility parses the statements and moves from batch to batch during the step execution process, each step controlled by you clicking the step execution button.

To use the Step Execute Facility

1. Open a script. For details, see Opening Files.
2. On the Query menu, select Step-Execute.

The procedure starts to execute and displays errors at the bottom of the Editor window. A toolbar offering subsequent step execution actions opens:

![Toolbar](image)

Note: Each executing line is indicated with a yellow arrow in the gutter of the Editor window. The gutter is that gray area between the line numbers on the left and the code window. As you step through your batches, the arrow moves to indicate your current location.

3. Use the following table as a guide to subsequent actions you take:
### Feature

<table>
<thead>
<tr>
<th>Step Executing a Script</th>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step</strong></td>
<td>Click the <strong>Step</strong> button to step into the next batch of code.</td>
<td></td>
</tr>
<tr>
<td><strong>Step Back</strong></td>
<td>Click the <strong>Step Back</strong> icon to step back to the most previous batch of code.</td>
<td></td>
</tr>
<tr>
<td><strong>Step Over</strong></td>
<td>Click the <strong>Step Over</strong> icon to jump over a batch to the next batch.</td>
<td></td>
</tr>
<tr>
<td><strong>Run to Cursor</strong></td>
<td>Click the <strong>Run to Cursor</strong> icon to execute all of the code between the beginning of the script to wherever you have inserted the pointer.</td>
<td></td>
</tr>
<tr>
<td><strong>Cancel Step Execution</strong></td>
<td>Click the <strong>Cancel Step Execution</strong> icon to change to regular execution mode.</td>
<td></td>
</tr>
<tr>
<td><strong>SQL Begin Transaction</strong></td>
<td>Toggles the Begin Transaction status on and off.</td>
<td></td>
</tr>
<tr>
<td><strong>SQL Rollback</strong></td>
<td>Performs a rollback on the current transaction.</td>
<td></td>
</tr>
<tr>
<td><strong>SQL Commit</strong></td>
<td>Commits the current transaction.</td>
<td></td>
</tr>
</tbody>
</table>

Keep the following in mind when using this feature:

- **ISQL Window Gutter**: The ISQL Window Gutter is a vertical gray display bar located to the left of the ISQL window. It includes location indicators such as line numbers, error indicators, and bookmarks. The gutter is a quick visual cue to your current position in the script.

- **Script Line Numbers**: Line numbers are included to let you navigate large scripts. Error messages in the output window indicate the line number where the error occurred.

- **Automatic Error Flagging**: When using the Step Execution mode, errors are flagged with a red dot in the ISQL window gutter. The errors are flagged sequentially as they are stepped into.

- **Point and Click Error Navigation**: Errors are displayed in the output window at the bottom of the screen and selects the errors as they occur. You can click each error and be taken directly to the line where that error occurred.
Using the Query Plan Facility

Each RDBMS platform lets you view the execution path that your SQL follows. For details, see the following topics:

- Viewing a Tree-based Query Plan (IBM DB2 for LUW, SQL Server, Sybase ASE)
- Viewing a Tree-based or Graphical Query Plan (Oracle)

Viewing a Tree-based Query Plan (IBM DB2 for LUW, SQL Server, Sybase ASE)

For IBM DB2 for Windows, Unix, and Linux, Microsoft SQL Server, and Sybase ASE, you can view a tree-based representation of a query plan. The Query Plan toolbar button is a toggle. Set it to enable the Show Plan mode.

The Query Plan window displays data for the estimated costs, number of rows, and bytes returned by each plan step.

Note: For IBM DB2 for Linux, Unix, and Windows, a tree view of statements and associated costs is included.

To view a tree-based representation of a query plan

1. Open a script.
2. On the Query menu, select Query Plan.

The Show Plan mode starts.
3. To generate the Show Plan in a separate result window, click Execute.

Viewing a Tree-based or Graphical Query Plan (Oracle)

For Oracle, you can view a graphical representation of a query plan. You can toggle the view between the graph-based view and a tree-based view, view details for each step, and work with a number of viewing options.

Note: The Options editor has a Default Query Plan setting that controls whether the default query plan display is tree-based or graphical. For details, see ISQL Options.

The Query Plan toolbar button is a toggle. Set it to enable the Show Plan mode.

To view a graphical representation of a query plan

1. Open a script.
2. On the Query menu, select Query Plan.

The Show Plan mode starts.
3. To generate the Show Plan in a separate result window, click **Execute**.

Options when working with the graphical Query Plan view include:

- Hovering the mouse over an execution step node to display detailed cost details for that step
- Right-clicking and choosing **Find Node** or **Find Next Node** to search large plans for nodes whose label contains a specified text string
- Right-clicking and choosing **Zoom In** or **Zoom Out**
- Right-clicking and choosing an **Orientation** sub-menu command to change the orientation of the view
- Right-clicking and choosing **Overview Window** to open a small window showing the entire plan
- Right-clicking and choosing **Save to File** to open a dialog that lets you save the graphical plan as a graphics file
- Clicking the **Query Plan** button to toggle between the graphical view and a tree-based view
- For multiple plans created from the same script/ISQL window, using the dropdown at the top of the plan to change the plan displayed

---

**Canceling a Query**

The ISQL Editor lets you cancel a query while the rows are still being returned.

**To Cancel a Query**

1. On the Editor window tool bar, click **Cancel**. For more information, see SQL Editor Toolbar Options.

**Note:** This button is only enabled after a script has begun executing.
Using the Results Editor

The results of your SQL queries are displayed in the Results tab of each Editor Window, which captures result sets in a virtual data grid that accommodates large result sets. The data grid offers many of the features of a basic Windows spreadsheet, giving you a great deal of flexibility in editing the worksheet and formatting its contents.

Tip: For Oracle, REF CURSOR contents are displayed in the ISQL Window and Results tab.

You have many choices for navigating and viewing your SQL query results. The Results window includes functionality to set result window options, find and replace, export data to other products such as Microsoft Excel, and mail your results files.

For more information, see Configuring Result Set Windows.

## Results Window Toolbar Options

The table below describes the options of the Results window toolbar:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Lock</strong></td>
<td>Lets you lock an ISQL Window to a specific datasource connection. When locked, the ISQL Window does not respond to datasource change events in other windows, and only uses the current connection for subsequent execution.</td>
</tr>
<tr>
<td><strong>Options</strong></td>
<td>Open the Options editor, letting you specify results window preferences. For more information, see <a href="#">Results (ISQL) Options</a>.</td>
</tr>
<tr>
<td><strong>ReExecute</strong></td>
<td>Lets you execute the script again without switching to the Query tab.</td>
</tr>
<tr>
<td><strong>Close</strong></td>
<td>Lets you close the current results window.</td>
</tr>
</tbody>
</table>
Configuring Result Set Windows

Result set windows can be configured in a variety of ways. You can configure your result set windows to present result sets in multiple or single panels, attached or detached from the corresponding ISQL window. These options can be set globally to save you the hassle of setting options for each result window. Additionally, Result windows can be torn off and dropped onto an open area of the workspace to create separate windows. These are known as Tear Off Tab Windows.

You can set the Result Window to display result sets in any of the following modes:

- Single result sets in one attached tab window.
- Multiple result sets in one attached tab window.
- Single result sets in one separate unattached tab windows.
- Multiple result sets in one separate unattached tab windows.

To configure result set windows

1. On the File menu, select Options.
2. In the Options Editor, click the list, and then click Results or click the Results tab.
3. Refer to Results (ISQL) Options for details on how to set result windows options.

Configuring Results Window Grid Properties

You can alter the physical appearance in a results set window. Effects include items such as 3-D buttons, highlighted headings, and enabled or disabled row and column gridlines.

To configure the appearance of result set grids

1. On the File menu, select Options.
2. In the Options Editor, click the list, and then click Grid Properties or click the Grid Properties tab.
3. Refer to Grid Properties (Results window) Options for details on how to set result windows options.
Exporting Data to Other Products

You can export data from a result set to traditional spreadsheet products, such as Microsoft Excel. You can copy part or all of a result set and paste it into your traditional spreadsheet product by way of the Microsoft Windows Clipboard function. You can also save your result sets as:

- Tab delimited files,
- Comma separated files
- Pipe delimited ('|') files
- HTML
- Excel 2000 or higher
- XML
- User-specified delimited files

Topics

- Using the Results Editor.
Setting Result Windows to Read-only Mode

To set your result windows to read only mode to keep anyone from accidentally editing or altering a result set, do the following:

1. Select a Result window that you want to make read only.
2. On the Edit menu, select Read Only.

A check-mark is placed next to read only.

Note: The Read Only command is a toggle. When it is set, the formatting buttons on the Edit menu are not available.

Topics

- Using the Results Editor

Result Window Status Bar

The Result Window Status Bar displays information about each Result window at the bottom of each window. You can display or hide the status bar by setting the Status Bar preference. This preference applies to all result windows.
Mailing Result Sets

If you have MAPI-compliant electronic mail software installed on your computer, then you can mail result sets to other users.

Mailing a Result Set

To mail a result set, do the following:

1. Open the Message dialog:
2. On the File menu, select Send.

The open Message dialog opens.
3. In the Address box, type the name of the addressee(s) and any other options.

The ISQL Editor automatically attaches a file containing your result set to the mail message.
4. Click Send.

The result set is sent to the specified addressee(s).

- Using the Results Editor
Renaming and Closing Query Window Tabs

SQL windows are tabbed windows that can be closed or renamed.

To rename a Query tab, you need an open SQL window that includes an executed script. For information on how to execute scripts, see Execution and Execution-related SQL Editor options.

Renaming a Query Window Tab

To rename a Query Window tab, do the following:

1. Right-click the Query tab on the SQL window, and then click Rename.

The Rename Tab dialog opens.

Note: The Query tab can be located on the top or bottom of the SQL window. You can set the location of the tab when configuring datasource options.

2. In the New Name box, type the name of the new Query window.

3. Click OK.

The name is changed and the Rename Tab dialog closes. The new name of the tab displays directly on the Query Window tab at the top of the window.

Closing a Query Window Tab

To close a Query Window tab, do the following:

1. At the top of the SQL window, right-click the Query tab, and then click Close or Close All.

The Query closes.
Closing Result Window Tabs

You can close tabbed Result set windows.

Closing a Result Window Tab

To close a Result Window tab, do the following:

1. On the Result Window tab tool bar, click Close.

OR

Right-click the Results tab, and then click Close.

The Result Window tab closes.

Topics

- Using the Results Editor.
Saving and Closing Result Sets

You can save your result sets using the standard Save and Save As functions. You can save multiple copies of the same result set and modify each copy to specific formatting requirements.

Saving Results

1. On the File menu, select Save. The Save Results dialog opens.
2. In the File name box, type the name of the result set.
3. From the Save as type dropdown, select a file type of Excel 2000 or later .xls, tab-delimited, comma-delimited, pipe-delimited, user-specified delimited .txt, HTML, or XML.
4. From the Encoding dropdown, select an encoding scheme of ANSI, UNICODE, UTF-16LE (No BOM), UTF-16 Big Endian, UTF-16BE (No BOM), UTF-8, UTF-8 (No BOM), UTF-32 Little Endian, UTF-32LE (No BOM), UTF-32 Big Endian, or UTF-32BE (No BOM).
5. To include column titles, select Include column titles when saving.
6. If you chose User Specified Delimiter, in User Specified Delimiter type the delimiter.
7. Click Save.

Closing a Result Set

To close a result set, do the following:

1. On the Main menu, click Close.

The Result Set closes.

2. If you have not saved your result set, you are prompted to save the file. Click Yes to save and No to close without saving.

Topics

- Using the Results Editor
Editing Result Sets

The Results Editor provides many ways to edit and customize your result windows. The Data Grid offers a host of features for manipulating, sorting and formatting data.

Topics

- Cutting, Copying, and Pasting Cell Contents
- Cutting, Copying, and Pasting Rows
- Cutting, Copying, and Pasting Columns
- Adding and Inserting Rows
- Adding and inserting columns
- Deleting Rows and Columns
- Resizing Rows and Columns
- Sorting Data

Cutting, Copying, and Pasting Cell Contents

The Result window supports standard cut, copy and paste functionality.

Cutting Cell Contents

To cut cell contents, do the following:

1. In the Results window, double click or tab to the target cell. A double line bounds the selected cell. You can also select text using standard text selection techniques.

2. On the Edit menu, select Cut.

Copying Cell Contents

To copy cell contents, do the following:

1. In the Results window, double click or tab to the target cell. A double line bounds the selected cell. You can also select text using standard text selection techniques.

2. On the Edit menu, select Copy.

Pasting Cell Contents

To paste cell contents, do the following:

1. In the Results window, double click or tab to the target cell. A double line bounds the selected cell.
2. On the **Edit** menu, select **Paste**.

**Cutting, Copying, and Pasting Rows**

You can perform standard cut, copy, and paste functions on rows, just as you can on individual cells.

**Cutting Rows**

To cut a row, do the following:

1. In the Results window, click the numbered row heading on the left side of the row.
2. On the **Edit** menu, select **Cut**.

**Copying Rows**

To copy rows, do the following:

1. In the Results window, double click or tab to the target row. A double line bounds the selected row. You can also select text using standard text selection techniques.
2. On the **Edit** menu, select **Copy**.

**Pasting Rows**

To paste rows, do the following:

1. In the Results window, double click or tab to the target row. A double line bounds the selected row.
2. On the **Edit** menu, select **Paste**.

**Cutting, Copying, and Pasting Columns**

You can perform standard cut, copy, and paste functions on columns, just as you can on rows.

**Cutting Columns**

To cut columns, do the following:

1. In the Results window, click the column heading above the first row.
2. On the **Edit** menu, select **Cut**.

**Copying Columns**

To copy columns, do the following:
1. In the Results window, click the column heading.

2. On the Edit menu, select Copy.

**Pasting Columns**

To paste columns, do the following:

1. In the Results window, click the column heading above the first row to select the target column.

2. On the Edit menu, select Paste.

**Adding and Inserting Rows**

You can add or insert rows to expand or rearrange your result sets.

**Adding a Row**

To add a row, do the following:

1. To add a row as the last row of the result set, position the pointer inside the result set.

2. On the Edit menu, select Add Row.

3. To add a row inside the result set, click the numbered row heading where you want to add a row.

4. On the Edit menu, select Add Row.

**Inserting a Row**

To insert a row, do the following:

1. To insert a row as the last row of the result set, position the pointer inside the result set.

2. On the Edit menu, select Insert Row.

3. To insert a row inside the result set, click the numbered row heading where you want to insert a row.

4. On the Edit menu, select Insert Row.

**Adding and inserting columns**

You can add or insert columns to expand or rearrange your result sets.
Adding a Column

To add a column, do the following:

1. Position the pointer inside the result set.
2. Select Edit, Add Column from the main menu. The new column is added as the last column of the result set.

Inserting a Column

To insert a column, do the following:

1. Select the column where you want to insert a column.
2. Select Edit, Insert Column from the main menu. The new column is inserted to the left of the column that you selected.

Deleting Rows and Columns

You can delete entire rows and columns to edit your result sets.

Deleting a Row

To delete a row, do the following:

1. Select the target row of data to delete.
2. On the Edit menu, select Delete Row.

Deleting a Column

To delete a column, do the following:

1. Select the target column of data to delete.
2. On the Edit menu, select Delete Column.

Resizing Rows and Columns

Resizing rows and columns can aid readability of the spreadsheet contents or condense space for editing and formatting purposes.

Resizing Rows to Their Default Height

To resize rows to their default height, do the following:

1. Select one or more rows by clicking on the numbered row headings to the left of the rows.
2. Right-click the selected rows, and then click Resize Rows.
Resizing Rows to a New Height

To resize rows to a new height, do the following:

1. Select one or more rows by clicking the numbered row headings to the left of the rows.
2. Change the pointer to a solid horizontal bar with arrows on top and bottom by moving it to one of the upper or lower borders of the row heading.
3. Click and grab the row border and drag the pointer to enlarge or shrink the height of the row.

Resizing Columns to Their Default Widths

To resize columns to their default widths, do the following:

1. Select one or more columns by clicking the column headings.
2. Right-click the selected columns, and then click Resize Columns.

Resizing Columns to a New Width

To resize columns to a new width, do the following:

1. Select one or more columns by clicking the column headings.
2. Change the pointer to a solid horizontal bar with arrows on top and bottom by moving it to one of the upper or lower borders of the column heading.
3. Click and grab the column border and drag the pointer to enlarge or shrink the height of the column.

Sorting Data

To order and organize data in a coherent manner, you can sort columns alphanumerically in single result sets.

Sorting Data

To sort data, do the following:

1. Double click the column header to sort the data in the column in ascending, alphanumerical order. To sort the column in descending order, double click the column header again.

Note: This option is not valid for multiple result sets.
Formatting Result Sets

The ISQL Editor provides flexibility in formatting result sets, for analysis and reporting, from within a Result Window. Result sets can be formatted to best suit your purpose, whether it be sending via e-mail, printing, or exporting a file to other programs, such as Microsoft Excel. Some of these features change only the screen display of the results, while others allow you to format for printing.

- Changing the Displayed View
- Format Border Styles
- Format Font Styles
- Format Color Styles

For information on general appearance of results, see Configuring Results Window Grid Properties.

Changing the Displayed View

You can view results in a standard grid, in HTML format, or as flat ASCII. By default, when a result window is generated, the results are displayed according to the view option currently selected on the Results (ISQL) Options. You can change the display in the results window.

To change the result view on the fly:

1. Right-click in the results window.
2. On the shortcut menu, choose one of the View as Grid, View as HTML, or View as ASCII options.

Format Border Styles

You can use the shortcut menu to alter border properties.

Completing the Format Styles Dialog Box

To complete the Format Styles dialog, do the following:

1. Right-click the Result data grid, and then click Border.
2. On the Border box, you can indicate whether or not a border should appear on the top, bottom, right, left, or for a range of cells by clicking the corresponding boxes.
3. To set a range of cells apart by setting a particular border style around that range, select the range in the result set before opening the Format Styles dialog. To select the Range property, click the range box.
4. In the **Type** box, you can select the type of line you want to border the cell or cells by clicking the corresponding boxes.

5. To select a color, click the **Color** list, and then click the border color.

6. Click **OK**.

Changes are saved and the **Format Styles** dialog closes.

**Format Font Styles**

You can use the shortcut menu to alter font properties. Selecting the Font command displays the **Format Styles** tabbed dialog.

**Completing the Format Styles Dialog Box**

To complete the **Format Styles** dialog, do the following:

1. Right-click the **Result** data grid, and then click **Font**.

The **Format Styles** dialog opens.

2. In the **Font** box, type or click the font you want to use.

3. In the **Style** box, type or click the font style you want to use.

4. In the **Size** box, type or click the size you want to use.

5. To make a line cross through the length of the text, in the **Effects** box, select the **Strikeout** check box.

6. To underline the text, in the **Effects** box, select the **Underline** check box.

7. To change the script style, click the **Script** list, and then click the new script style.

The Sample box displays the sample text of your selections.

**Format Color Styles**

You can use the shortcut menu to alter color properties. Selecting the Color command displays the **Cell Properties** dialog.

**Completing the Cell Properties Dialog Box**

To complete the **Format Styles** dialog, do the following:

1. Right-click the **Result** data grid, and then click **Color**.

The **Cell Properties** dialog opens.

2. Change the **Text Color** and **Background Color** options.
Notes on XML Types and Unicode Display in the Results Editor

When viewing data in the Results grid, keep the following in mind:

- XML data types are supported for IBM DB2 for Windows, Unix, and Linux, Microsoft SQL Server, and Oracle. In the Results grid, XML data types are displayed as LOB content.

- Support for display of Unicode characters is provided as follows:
  - IBM DB2 for Windows, Unix, and Linux V8 and V9: character, clob, varchar, and longvarchar types
  - SQL Server 2005: nchar, nvarchar, ntext, and nvarchar(max) types
  - Oracle 9i, and 10g: NCHAR, NVARCHAR2 and NCLOB for non-Unicode UTF8 Character Set Instances and NCHAR, NVARCHAR2, CHAR, VARCHAR2, LONG, NCLOB and CLOB for Unicode UTF8 Character Set Instances
  - Sybase ASE 12.5 and 15.2: UNICHAR, UNIVARCHAR and UNITEXT for non-Unicode UTF8 Character Set Instances and UNICHAR, UNIVARCHAR, UNITEXT, NCHAR, NVARCHAR, CHAR, VARCHAR and TEXT for Unicode UTF8 Character Set Instances
Miscellaneous SQL Editor Tasks

The following supplementary function is available from the SQL Editor:

Emailing SQL Scripts

If you have MAPI-compliant E-mail software installed on your computer, then you can send SQL scripts to other users.

To send a SQL script

1. Open a SQL Editor and open, paste, or type a script. For more information, see Using the SQL Editor.

2. On the File menu, select Send. Your E-mail application opens and automatically attaches a file containing the script.

3. In the Address box, type the name of the addressee(s) and when ready click Send.
Using the DDL Editor

You use the DDL Editor when you want to create a script that is tied to an object type in your database. The DDL Editor opens containing a template script for the selected object type. Because the DDL Editor is directly tied to a database, database warning messages can be issued. For example, if you have a create table script which includes a DROP TABLE statement, the DDL Editor warns you about the existence of this statement and that you could lose existing table data.

Tip: Since you must drop a database object before you can recreate it, you can set the DDL Editor to automatically include DROP statements for specified objects. For more information, see the DBMS platform-specific topics under DDL Extract Options.

To create an object using the DDL Editor

1. On the File menu, select New > DDL Editor.
2. Use the following table as a guide to completing the dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Type</td>
<td>Lets you select the object type to which you want to attach the script.</td>
</tr>
<tr>
<td>Owner</td>
<td>Lets you type the name of the object owner for the object. The name of the owner connected to the current datasource is used as the default.</td>
</tr>
<tr>
<td>Object Name</td>
<td>Lets you type the name of the object type.</td>
</tr>
</tbody>
</table>

1. Click OK.

The DDL opens in the SQL Editor. A subset of SQL Editor functionality becomes available. For more information, see Using the SQL Editor.
Data, Schema, and Miscellaneous Utilities

DBArtisan incorporates a number of powerful utilities that let you create, edit and manage your development environment. Primarily schema and data-oriented, there also server configuration, session-specific, and process-specific utilities. The following table lists available utilities and their availability by DBMS platform.

<table>
<thead>
<tr>

Archive activity (ORCL)

Oracle uses Redo logs to record changes made to a database during operation. These files, which are active or online during normal operation, are referred to as the online redo logfiles. Oracle uses these files to reapply changes made during the recovery process that were not written to datafiles before shutdown. You can operate an Oracle database in ARCHIVELOG or NOARCHIVELOG mode. If you choose ARCHIVELOG mode, then Oracle uses a background process to copy the contents of the online redo logfiles as archive redo logfiles in a separate area. ARCHIVELOG mode lets you perform online backups and database media recovery of your Oracle database.

The Archive Activity Monitor lets you to analyze the status, activity levels, proper sizing and performance of your archive redo logs. At a glance, you can determine the ARCHIVELOG mode, configuration and vital statistics about redo log performance. In particular, the Archive Activity Monitor lets you to assess whether or not the redo logfiles are sized properly. It is very important to choose the right size for online redo logfiles. If the redo logs are too small, the Log Writer must switch logfiles too often, which hurts performance. If the redo logs are too big, recovery times are longer.

The table below describes the Archive Activity Monitor options:

<table>
<thead>
<tr>
<th>Category</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log Archiving</td>
<td>Log Mode</td>
<td>Whether or not ARCHIVELOG mode is active for the Oracle instance.</td>
</tr>
<tr>
<td></td>
<td>Auto Archival</td>
<td>Whether or not the database has been configured to archive redo logs automatically.</td>
</tr>
<tr>
<td></td>
<td>Destination</td>
<td>Directory where the archive redo logs are contained.</td>
</tr>
<tr>
<td></td>
<td>Oldest Log Sequence</td>
<td>Oldest system change number. As a precaution, your backups should include all archived logfiles starting with the oldest log sequence.</td>
</tr>
<tr>
<td></td>
<td>Current Log Sequence</td>
<td>Current system change number. It marks the start of the backup.</td>
</tr>
<tr>
<td>Online Redo Archive</td>
<td>Redo Entries</td>
<td>Number entries made to the online redo logs by the Log Writer (LGWR) process.</td>
</tr>
<tr>
<td></td>
<td>Avg Redo Size</td>
<td>Average size, in kilobytes, of a redo log entry.</td>
</tr>
</tbody>
</table>
### Archive Activity (ORCL)

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redo Log Buffer Contention</td>
<td>Number of entries made to the redo log buffer by the Log Writer (LGWR) process.</td>
</tr>
<tr>
<td>Entry Requests</td>
<td>Number of times that the Oracle Log Writer has had to wait before making an entry to the redo log buffer. This number is accumulated since the last time that the database was started. A high number of waits indicates that the log buffer size is too small. To increase the size, you need to modify the LOG_BUFFER parameter in the Oracle configuration file (e.g., INITORCL.ORA).</td>
</tr>
<tr>
<td>Entry Wait Times</td>
<td>When the redo log switch occurred. If redo log switches occur frequently, the redo logs are probably too small. As a rule-of-thumb, redo log switches should not occur more frequently than once every 30 minutes. If they are occurring more frequently, then you should increase the size of the redo logs.</td>
</tr>
<tr>
<td>Redo Log Switches Time</td>
<td>Displays ID number in the control file.</td>
</tr>
<tr>
<td>Record ID in Controlfile</td>
<td></td>
</tr>
</tbody>
</table>

#### Opening the Archive Activity Dialog Box

1. On the **Utilities** menu, click **Archive Activity**.

DBArtisan opens the **Archive Activity** dialog.
Backup Control Files (ORCL)

You should keep many copies of your control files to safeguard against disk failure or loss of the primary control file. DBArtisan provides a graphical interface for constructing the ALTER DATABASE command needed to backup your control files.

Using the Backup Control Files Utility

1. On the Utilities menu, click Backup Control File.

DBArtisan opens the Backup Controlfile Dialog Box.

Backup Controlfile Dialog Box

The table below describes the options and functionality available on the Backup Controlfile dialog.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Backup Controlfile Name</td>
<td>Type the name of the backup control file in the box. To reuse an existing</td>
</tr>
<tr>
<td></td>
<td>Back Up Controlfile, type the name of the existing file, and then select</td>
</tr>
<tr>
<td></td>
<td>Reuse Existing Backup Controlfile. NOTE: When you type in the Backup</td>
</tr>
<tr>
<td></td>
<td>Controlfile Name box, the check box is activated.</td>
</tr>
<tr>
<td>Reuse Existing Backup</td>
<td>Select this check box if you want to reuse an existing file. The name of</td>
</tr>
<tr>
<td>Controlfile check box</td>
<td>the file and the name entered in the Backup Controlfile Name box must be the</td>
</tr>
<tr>
<td>Trace SQL Statements</td>
<td>Click the option button that corresponds to how you want Trace SQL</td>
</tr>
<tr>
<td></td>
<td>statements handled: None - No statements are traced. Reset Logs - Traces</td>
</tr>
<tr>
<td></td>
<td>reset logs. No Reset Log - Does not trace reset logs.</td>
</tr>
</tbody>
</table>
Chained Row Analysis (ORCL)

Updates can cause data rows to migrate and to chain over multiple data blocks. Chaining degrades performance because more physical reads are required to access a row of data. Consequently, you should monitor chained rows regularly to spot performance bottlenecks before they become severe.

To avoid chained rows, you can tune the Percent Free storage settings for that table or cluster. By increasing the Percent Free on each data block, you decrease the likelihood that an update causes a data row to expand over multiple data blocks.

If the row length is greater than the size of a data block, you cannot avoid chained rows.

DBArtisan provides a utility that lets you identify chained rows quickly by displaying chained rows for all or any schema in your Oracle database.

Analyzing Chained Rows

1. On the Utilities menu, select Chained Row Analysis.

DBArtisan opens the Chained Row Analysis dialog.

The table below describes the options and functionality on the Chained Row Analysis dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>Lets you select the owner for whom you want to scan for chained rows.</td>
</tr>
<tr>
<td>Refresh Button</td>
<td>Click to refresh the list.</td>
</tr>
</tbody>
</table>

Chained Row Analysis (ORCL)
Data Export (DB2 LUW)

The Export Utility lets you use the Command Line Processor EXPORT command to export data. A wizard lets you generate two CLP calls:

- A CONNECT command to connect to the server
- An EXPORT command

Wizard controls let you specify a full set of EXPORT parameters.

**Note:** Before using this utility, you must specify the location of executables used by DB2. For details, see [DB2 Utilities Options](#).

To export data from a DB2 LUW database

1. Connect to a DB2 LUW datasource and ensure that it is the currently selected datasource. For details, see [Connected/Selected Datasource options](#).
2. Select **Utilities > Export** to open the CLP Export Wizard.
3. Use the following table as a guide to performing tasks as you pass through the wizard panels:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Options</td>
<td>Export file type</td>
<td>Lets you select among <strong>DEL</strong> (delimited ASCII format), <strong>WSF</strong> (work sheet format), and <strong>IXF</strong> (Integration Exchange Format), output file formats.</td>
</tr>
<tr>
<td></td>
<td>Export file name</td>
<td>Lets you specify the name of the file to which data is to be exported.</td>
</tr>
<tr>
<td></td>
<td>Messages file name</td>
<td>Lets you specify the name of the file to which warning and error messages occurring during an export operation will be written.</td>
</tr>
<tr>
<td>IXF Specific File Options</td>
<td>If an Export file type of IXF was selected, this control lets you provide a Code page of the data in the output data set (codepage=) value</td>
<td></td>
</tr>
<tr>
<td>DEL Specific File Options</td>
<td>If an Export file type of DEL was selected, this group of controls lets you specify a set of type modifiers (corresponding to modifiers such as CHARDEL, COLDEL, DECPT, DECPLUSBLANK, NODOUBLEDEL, NOCHARDEL, STRIPLZEROS and TIMESTAMPFORMAT), specifying delimiter and general character conventions.</td>
<td></td>
</tr>
<tr>
<td>WSF Specific File Options</td>
<td>If an Export file type of WSF was selected, this group of controls corresponds to valid type modifiers for worksheet (1-4) Lotus and DBCS formats.</td>
<td></td>
</tr>
<tr>
<td>General Options</td>
<td>Separate the LOB data from the data file</td>
<td></td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Selecting this check box adds a LOBSINFILE modifier and activates other LOB-related controls in the group.</td>
<td></td>
</tr>
<tr>
<td>LOB Paths</td>
<td>Lets you build a list of LOBS TO clause values, specifying one or more paths to directories where LOB files are to be stored.</td>
<td></td>
</tr>
<tr>
<td>LOB Filenames</td>
<td>Lets you build a list of LOBFILE option values, specifying one or more files where LOBs are to be stored.</td>
<td></td>
</tr>
<tr>
<td>Place each LOB in a separate file</td>
<td>Adds a LOBSINSEPFILES modifier, specifying that each LOB value is to be written to a separate file.</td>
<td></td>
</tr>
<tr>
<td>XML Path</td>
<td>Lets you build a list of XML TO clause values, specifying one or more paths to directories where XML files are to be stored.</td>
<td></td>
</tr>
<tr>
<td>XML Filename</td>
<td>Lets you build a list of XMLFILE option values, specifying one or more XML file names.</td>
<td></td>
</tr>
<tr>
<td>Save XML schema information for all XML columns</td>
<td>Selecting this check box adds a XMLSAVESCHEMA modifier, specifying that XML schema information should be saved for all XML columns.</td>
<td></td>
</tr>
<tr>
<td>Write each XQuery Data Model (XDM) instance to a separate file</td>
<td>Selecting this check box adds a XMLINSEPFILES modifier, specifying that each XDM instance is written to a separate file</td>
<td></td>
</tr>
<tr>
<td>Write XDM instances without an XML declaration tag</td>
<td>Selecting this check box adds a XMLNODEDECLARATION modifier, specifying that XDM instances are written with no XML declaration tag.</td>
<td></td>
</tr>
<tr>
<td>Encode XML documents in the UTF-16 code page</td>
<td>Selecting this check box adds a XMLGRAPHIC modifier, specifying that exported XML documents are encoded in the UTF-16 code page regardless of the application code page or codepage file type modifier.</td>
<td></td>
</tr>
<tr>
<td>Use the application/the specified code page to write XDM instances</td>
<td>Selecting this check box adds a XMLCHAR modifier, specifying that</td>
<td></td>
</tr>
</tbody>
</table>
When exporting data from a DB2 LUW database, this panel lets you specify the data to be exported. SELECT, XQUERY, HIERARCHY, and HIERARCHY STARTING options are provided. To specify a SELECT or XQUERY statement export, select the select or xquery statement radio button. In the Specify the statement to use for export box, provide text of the SELECT or XQUERY statement. Optionally, use the Method N controls (New, Delete, Move Item Up, Move Item Down) to provide a list of column names to be used in the output files. To specify a default traverse order, select the hierarchy with the default traversal order radio button. From the Select the start table for the hierarchy list, select the table that the export hierarchy is to start from. To specify a user-provided traverse order, select the hierarchy with user specified traversal order radio button. In the Double-click on table... list, double click on each table to be included in the traversal order list. The selected tables are displayed in the Custom traversal order... list. Use the controls associated with the Custom traversal order... list (Delete, Move Item Up, Move Item Down) to order the list. In the Where clause box, provide a condition specifying which rows are exported.

4. Finally, use the Execute button to perform the backup.
Data Load

The Data Load utility is available for a number of platforms:

- Data Load (DB2 z/OS)
- Data Load (DB2 LUW)
- Data Load (SQL SVR, SYB ASE)
- Data Load (PostgreSQL)
Data Load (DB2 z/OS)

The DBArtisan Load Data Utility for DB2 z/OS enables you to load records into one or more tables in a tablespace without creating an intermediate exported file. If the tablespace already contains data, you can opt to add the new data to the existing data or to replace it. The data that's loaded is subject to the same editing or validation routines currently associated with the table and any field procedure associated with particular table columns. As output, you get a loaded tablespace or partition, a file of records that have been discarded, and an error report if you specify the Enforce Constraints option or if unique indexes were part of the load operation.

To use this utility, you need a sufficient set of privileges.

One of the following conditions must be met:

- You must own the table
- Have load privileges for the database
- DBAdmin or DBCTRL authority for the database.
- SYSCTRL or SYSADM authority.

Refer to IBM documentation for details on utilities. For assistance, see Accessing Third Party Documentation.

To Open the Load Data Utility Wizard

1. Connect to a DB2 OS390 database on the Navigator/Explorer tree.
2. Expand the database and click the Tablespace subnode.
3. In the right window, select a tablespace and click Load Data from the Command drop-down menu.
4. Use the following topics as a guide to completing the pages of the wizard.
## Initial Settings

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do you want the utility to be restartable?</td>
<td>The utility restart information will be included if a recover operation is required.</td>
</tr>
<tr>
<td>Tape Stacking</td>
<td>Select this if you are backing up this operation onto physical media. Click Properties to specify the particulars for the dataset as it’s recorded by opening the Load Utility - Tape Stacking Dialog Box.</td>
</tr>
<tr>
<td>Do you want to specify a cursor?</td>
<td>If you want to specify a cursor you need to type the name of the cursor for the input data set in the field below. No is the default. Any cursor name you specify cannot exceed eight characters.</td>
</tr>
<tr>
<td>Specify the In DDN</td>
<td>The input template name. SYSREC is the default.</td>
</tr>
<tr>
<td>Would you like to preformat?</td>
<td>If you say yes, you are telling the operation to serialize at the tablespace level. This can inhibit concurrent processing of separate partitions. No is the default.</td>
</tr>
</tbody>
</table>

## Resumption/ Replace/Statistics

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resume</td>
<td>If you say No, records load into an empty tablespace. This is the default. If you say Yes, records are loaded into a non-empty tablespace. Loading begins at the current end of data in the tablespace. If you specify the sharelevel as change, the before and after triggers for each row that’s loaded are activated. The default sharelevel is none--this specifies that applications cannot concurrently access the tablespace during the load operation. When you select Yes, the remaining options on this panel are unavailable.</td>
</tr>
<tr>
<td>Replace</td>
<td>Here you indicate whether the tablespace and its indexes need to be reset to empty before records load. If you select Yes, you are telling the load operation to serialize at the tablespace level. No is the default.</td>
</tr>
<tr>
<td>Would you like to specify the statistics option?</td>
<td>Here you indicate whether you want to gather statistics for the tablespace. No is the default. If you select Yes, statistics are gathered on a base tablespace, but not an LOB tablespace. If you gather statistics on encrypted data, the results may not be useful.</td>
</tr>
<tr>
<td>Do you want to output message to SYSPRINT?</td>
<td>This is the output dataset for messages and printed output. Default is the default.</td>
</tr>
<tr>
<td>Do you want to force aggregation or rollup processing to be done even though some parts do not contain data?</td>
<td>Yes, No, or default. Default is the default. Here you specify whether you want statistics to aggregate or rollup when RUNSTATS is executed even in the event that some parts are empty.</td>
</tr>
</tbody>
</table>
Select Tables (for running statistics)

Here you are presented with a dialog box where you identify the table you want to run statistics on. Click ADD to open the Table/Object Selector dialog. Click Set Properties to open the Select Column for Table dialog. Click Delete to remove a table you selected from the run statistics operation.

Select Tables to Load Data Into

Here you are presented with the dialog box where you identify the tables you want to load the data into. Click ADD to select one or more tables. Click Set Properties to open the Into Table Specification Dialog Box.

Select Indexes

Here you are presented with a dialog box where you identify the indexes you want to run statistics on. Click ADD to open the Index/Object Selector dialog. Click Set Properties to open the Set Correlation option dialog where you set the KeyCard and Frequent Item options. When you ADD Frequent Options, the Add Frequent Options dialog opens which identifies the number of columns and the count.
### Update/History Statistics

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Update Statistics</strong></td>
<td>All: Indicates that all collect statistics are to be updated in the catalog. All is the default. Access Path: Indicates that updates are to be made only to the catalog table columns that provide statistics used for selecting the access path. Space: Indicates that updates are to be made only to the catalog table columns that provide statistics that help assess the status of a particular tablespace or index. None: Indicates no catalog tables will be updated. Note: This is enabled only when the Report option is set to Yes.</td>
</tr>
<tr>
<td><strong>History Statistics</strong></td>
<td>This records all catalog table inserts or updates to the catalog history tables. Default: The value specified on All: Indicates all collected statistics are to be updated in the catalog history tables. Access Path: Indicates that updates are to be made only to the catalog history table columns that provide statistics used for selecting the access path. Space: Specifies that only space-related statistics are to be updated in catalog history tables. None: Specifies that no catalog history tables are to be updated with the statistics that have been collected.</td>
</tr>
</tbody>
</table>

### Dictionary/Log

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Keep dictionary</strong></td>
<td>If you specify No, the load operation is prevented from building a new compression dictionary, thereby saving you the costs related to such a build operation. No is the default.</td>
</tr>
<tr>
<td><strong>Reuse</strong></td>
<td>When used with Replace (on an earlier panel of the wizard), this option indicates that the load operation should reset and reuse the datasets without deleting or refining them. No is the default.</td>
</tr>
<tr>
<td><strong>Log</strong></td>
<td>The Default specifies normal logging during the load operation and is equivalent to Yes. All loaded records will be logged. No specifies no logging of data in the load operation and disables the copy-pending option below.</td>
</tr>
<tr>
<td><strong>LOAD is not to set the tablespace in the COPY-pending status</strong></td>
<td>This, the NOCOPYPEND option will not turn off any copy pending options set prior the load operation. NOTE: Specify this option only if the data in this table can be recreated by another load operation if, for some reason, the data is lost. You may not be able to recover the tablespace if you don’t take an image copy after the load operation. No is the default.</td>
</tr>
</tbody>
</table>

### Enforce/Specify
<table>
<thead>
<tr>
<th><strong>Required Information</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Enforce</td>
<td>Specifies whether the load operation should enforce check and referential constraints. Constraints indicates constraints will be enforced. If the operation detects a constraint violation, the errant row is deleted and identified by a message. If you elect this option, and there are referential constraints, you must define sort input and output datasets. Default enforces the constraints. No specifies constraints are not enforced. It also puts the tablespace in the Check-pending status if at least one referential or check constraint exists.</td>
</tr>
<tr>
<td>Would you like to specify the Work DDN?</td>
<td>If you elected to enforce constraints, you must specify the work DDN. Here you establish DD names for the temporary sort input and output files. The default input is SYSUT1 and output is SORTOUT.</td>
</tr>
<tr>
<td>Would you like to specify the SORTKEYS?</td>
<td>This specifies that the index keys are to be sorted in parallel during the sort build phase to improve performance. If you want, you can specify an integer value to provide an estimate of the number of index keys that are to be sorted. The default is 0 if the input is on tape or a cursor.</td>
</tr>
<tr>
<td>Format</td>
<td>This selection is for the format of the input data. Unload specifies that the input record format is compatible with DB2 unload format. SQL/DS indicates the input record format is compatible with SQL/DS format.</td>
</tr>
</tbody>
</table>
## Input/CCSID

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input data file type</td>
<td>Select between EBCDIC, ASCII, or Unicode.</td>
</tr>
<tr>
<td>CCSID(s)</td>
<td>These coded character set identifiers for the input file generally correspond to the input data file type. If that’s not the case, the input data will be converted to the table CCSIDs before being loaded.</td>
</tr>
<tr>
<td>Do not accept substitution characters in a string</td>
<td>Specifies that the load operation should not accept substitution characters in the string. Use substitutions when a string is being converted from one data type to another. If you do not accept substitutions and the load operation determines that a substitution appears in the string because of a conversion, if discard processing is active, the record will be moved to the discard file. If discard processing is inactive, the load operation will terminate.</td>
</tr>
<tr>
<td>Float</td>
<td>S390 specifies that the load operation should expect floating point numbers are in the System/390 hexadecimal floating point format. IEEE specifies that the load operation should expect that floating point number are in IEEE binary floating point format. If you specify IEEE, the binary format floats will be converted to hexadecimal floating points. If there’s a conversion error, the record goes in the discard pile.</td>
</tr>
<tr>
<td>Specify the error DDN</td>
<td>Here you specify the DD statement or template for a work dataset that’s used during error processing. SYSERR is the default.</td>
</tr>
</tbody>
</table>

## Map DDN/Discard DDN

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Would you like to specify the Map DDN?</td>
<td>Specifies the DD statement or template for a work data set to be used in error processing. This is used to correlate the identifier of a table row with the input record that’s causing the error. SYSMAP is the default.</td>
</tr>
<tr>
<td>Would you like to specify the Discard DDN?</td>
<td>Specifies the DD statement or template for a discard dataset that will hold copies for records that aren’t loaded in the operation (e.g., a record with a conversion error). SYSDISC is the default.</td>
</tr>
<tr>
<td>Would you like to specify the maximum number of source records to be written on the discard data set?</td>
<td>Specify an integer with a value between 0 and 2146483647. If the maximum value is reached, the load operation abnormally terminates. When you enter 0, you are specifying that you do not want to set a maximum value and the entire input data set can be discarded.</td>
</tr>
<tr>
<td>Would you like to specify the sort device type?</td>
<td>Here you indicate, if available, the device type for temporary datasets that are to be dynamically allocated by DFSORT.</td>
</tr>
</tbody>
</table>
## Specify Sort Number/CONTINUE-IF

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do you want to specify the sort number?</td>
<td>This is the number of temporary datasets that will be allocated by the sort application program.</td>
</tr>
<tr>
<td>Would you like to specify a CONTINUE-IF condition?</td>
<td>Yes indicates that you want to treat each input record as a portion of a larger record. If a record is true, the next record is concatenated with it before it is loaded.</td>
</tr>
<tr>
<td>Start/Finish</td>
<td>Specifies the column numbers of the first and last columns.</td>
</tr>
<tr>
<td>Hexadecimal</td>
<td>The byte-string value in the continuation field indicates that the next input record is a continuation of the current load record. Records with this byte-string value are concatenated until the value in the continuation field changes.</td>
</tr>
<tr>
<td>Condition</td>
<td>After the CONTINUE-IF completes, write a condition as X’byte-string’ or ‘character-string’</td>
</tr>
</tbody>
</table>

## Into Table Specification Dialog Box

At least one table INTO STATEMENT is required for each table that is to be loaded. Each Into Table Specification:

- Identifies the table that is to be loaded.
- Describes fields within the input record.
- Defines the format of the input dataset.

**Note:** All tables that are specified must belong to the same tablespace.
<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skip fields in the input data set that do not correspond to columns in the target table</td>
<td>Specifies whether or not the load operation should skip fields in the input dataset that do not correspond to columns in the target table.</td>
</tr>
<tr>
<td>Partition</td>
<td>An integer value that applies to the number of the partition where records are to be loaded. This is an option that is enabled only for partitioned tablespaces.</td>
</tr>
<tr>
<td>Would you like to preformat?</td>
<td>Specifies that any remaining pages should be preformatted up to the high-allocated RBA in the partition and its corresponding partitioning index space. Preformatting happens after the data is loaded and the indexes are built.</td>
</tr>
<tr>
<td>Load records into a non-empty partition</td>
<td>No loads records into an empty partition. No is the default. Yes loads records into a non-empty partition. If the partition is empty, you get a warning message, but the partition is loaded anyway.</td>
</tr>
<tr>
<td>Replace only the contents of the partition specified above, rather than the entire tablespace.</td>
<td><strong>Note:</strong> You cannot use Load Replace with the partition integer replace option. You can either replace an entire tablespace using the load replace option or the single partition option here.</td>
</tr>
<tr>
<td>Reset and reuse DB2-managed data sets</td>
<td>When used with the replace option above, this specifies that the load operation should reset and reuse the DB2-managed datasets without deleting and redefining them.</td>
</tr>
<tr>
<td>Would you like to keep the dictionary?</td>
<td>This is an option only if a dictionary exists and the partition being loaded has the COMPRESS YES attribute. If the partition has the COMPRESS YES attribute but no dictionary exists, a dictionary is built and you get an error message.</td>
</tr>
<tr>
<td>Would you like to specify a cursor?</td>
<td>If desired, specify a cursor for the input dataset.</td>
</tr>
<tr>
<td>Select statement for cursor</td>
<td></td>
</tr>
<tr>
<td>In DNN</td>
<td>Specifies the data definition statement or template for the input dataset for the partition. The default is SYSREC.</td>
</tr>
<tr>
<td>Discard DNN</td>
<td>Specifies the data definition statement or template for the partition. This dataset also holds copies of records that were loaded and removed. It must be a sequential data set.</td>
</tr>
</tbody>
</table>

Page 2:
Do you want to set criteria for which records are loaded? If you do not want to specify load criteria, all records in the input dataset are loaded, except for data that is beyond the range of the specified partition.

Do you want to use field selection criteria? Yes or No.

SQL/DS Table Owner: Select a table owner from the drop-down list. Table: This is the name of the table that the SQL/DS table is loaded into.

Field selection Criteria The criteria describes a field and a character constant. A field must contain a character or graphic string. (When compared to a string constant, no datatype conversions are performed.) If the field and the constant are not the same length, the shorter of the two is padded with blanks before a comparison is made.

Fields Click Add to open the Field Specification Dialog Box.

Field Specification Dialog Box

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field Name</td>
<td>The name of a field defined by a field specification. This can be any name you choose.</td>
</tr>
<tr>
<td>Would you like to specify a position?</td>
<td>Indicates where a field appears in the assembled load record. Start/End are the locations of the first and last field records. The first record is column 1.</td>
</tr>
<tr>
<td>Datatype</td>
<td>Pick the appropriate datatype from the drop-down list.</td>
</tr>
<tr>
<td>Length/Scale</td>
<td>Length is the length in bytes of the input field. Scale is the number of digits to the right of the decimal point and must be greater than or equal to 0. 0 is the default.</td>
</tr>
<tr>
<td>Would you like to add a condition that causes the db2 column to be loaded with NULL or it’s default value?</td>
<td>NULLIF/CONDITION: Write a condition that causes the DB2 column to be loaded with NULL. DEFAULTIF/CONDITION: Write a condition that causes the DB2 column to be loaded with its default value. No</td>
</tr>
</tbody>
</table>

Set Dataset Info Dialog Box
### Data Load (DB2 z/OS)

<table>
<thead>
<tr>
<th>Required Information</th>

</table>

### Load Utility - Tape Stacking Dialog Box

Tape stacking allows you to make four copies of the same data set simultaneously. DB2 OS390’s Copy to Copy utility allows you to make multiple image copies as well.
<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local Site Primary Copy</td>
<td>Name the data set where you want the output image copy to go at the local primary site. This relates to the copyddn1 parameter in the stored procedure.</td>
</tr>
<tr>
<td>Local Site Backup Copy</td>
<td>Name the data set where you want the output image copy to go at the local backup site. This relates to the copyddn2 parameter in the stored procedure.</td>
</tr>
<tr>
<td>Recovery Site Primary Copy</td>
<td>Name the data set where you want the output image copy to go at the recovery primary site. This relates to the recoveryddn1 parameter in the stored procedure.</td>
</tr>
<tr>
<td>Recovery Site Backup Copy</td>
<td>Identify the image set where you want the image copy to go at the recovery backup site. This relates to the recoveryddn2 parameter in the stored procedure.</td>
</tr>
<tr>
<td>In DDN</td>
<td>Identify the input data set that contains the table to be loaded.</td>
</tr>
<tr>
<td>Discard DDN</td>
<td>Identify the work data set that will hold copies of records not included in the load operation.</td>
</tr>
</tbody>
</table>
Data Load (DB2 LUW)

DBArtisan offers a simple, six-panel wizard that lets you load data via DBArtisan’s import utility. After defining the data import operation, you have the opportunity to save the job definition for future reuse.

Starting the Import Wizard

1. Connect to the datasource to which data is to be imported and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Data Load. The Data Import Wizard opens.

3. Use the following table as a guide to providing details as you proceed through the wizard.
<table>
<thead>
<tr>
<th>Step</th>
<th>Panel</th>
<th>Options/Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Do you wish to initiate a new import operation or ‘play back’ a previously saved operation?</td>
<td>New Data Load Operation - Select to define a new data load operation. Previous Data Load Operation - Select to open a previously defined schema extraction operation. In the Data Load Definition File Name box, type the location and name of the job file or click the browse button.</td>
</tr>
<tr>
<td>2</td>
<td>What file has the data you wish to import?</td>
<td>Lets you type the location and name of the file or click the browse button. <strong>Specify the format of the file to be imported</strong> - Lets you click the list and click the file format. Options Button - Click if you want to set the ASCII file type options for a delimited option. <strong>What mode would you like to use for this import operation?</strong> - Choose a mode: INSERT - The target table must exist and imported rows are inserted into the table without affecting existing rows in the table. INSERT_UPDATE - The target table must exist and have primary key constraint defined on it. Imported rows that match the existing row of data on which the primary key is defined are updated. New rows that do not match the primary key are inserted into the table. REPLACE - The target table must exist and all data is replaced with the contents of the import data file. CREATE - The table defined in the import data file is created and rows of data are inserted into the newly created table. You must use a *.IXF file to use this mode. REPLACE_CREATE - If the target table exists, the data will be replaced with the data contained in the import data file and the table definition remains unchanged. If the target table does not exist, the table defined in the import data file is created and rows of data are inserted into the newly created table. You must use a *.IXF file to use this mode. <strong>What is the target object into which the data will be imported?</strong> - Use one of the following: DATABASE- Lets you select the database. SCHEMA - Lets you select the schema. OBJECT - Lets you select the table or view.</td>
</tr>
<tr>
<td>3</td>
<td>What method should be used for selecting columns for the export file?</td>
<td>Lets you specify a method: Default, Position, Location, or Names. Indicate the columns into which data should be imported, specifying the relevant column selection attributes - Lets you select the columns. Click <strong>Edit</strong> to open the Column Position Attributes dialog. <strong>Include</strong> - Select to include the column. <strong>Position</strong> - Lets you type the position.</td>
</tr>
<tr>
<td>4</td>
<td>Would you like to retrieve large objects (LOB’s) from separate files?</td>
<td>Specify LOB options: Add Button - Click to open the Browse for Folder dialog. Click the LOB path. Edit Button - Click to open the Browse for Folder dialog. Remove - Click to remove the LOB path. <strong>Specify a path and name for the message file</strong> - Type the directory location of the message file or click the Browse button to find the file.</td>
</tr>
<tr>
<td>5</td>
<td>How many of the file’s records should be skipped before the import begins?</td>
<td>RESTART lets you type the value of the number of rows that should be skipped before the import operation begins. How many records should be imported before committing them to the database? - COMMENT RECORDS lets you type the value of the number of records that should be imported before they are committed to the database. <strong>Use of Compound SQL may improve performance.</strong> - STATEMENTS lets you type the value of the number, which cannot exceed 100, of the number of SQL statements per compound block.</td>
</tr>
</tbody>
</table>
6  Do you wish to re-use this data unload operation? - To re-use the operation, type the location and name of the data load definition file or click the Browse button. DBArtisan gives the operation a default extension of *.LOAD.

7  Review the data load operation description to verify its accuracy. To make any changes, click Back to scroll back to the appropriate panels of the wizard to make your corrections.

4. When ready, click Execute.

Data Load (SQL SVR, SYB ASE)

DBArtisan offers a simple, six-step wizard that can load data via Microsoft SQL Server's BCP (bulk copy program) utility or via Sybase ASE's BCP (bulk copy program) utility. After defining the data import operation, you have the opportunity to save the job definition for future re-use.

Tip: For related information, see Data Unload (SQL SVR, SYB ASE).

To load table data

1. Connect to the datasource where the data is to be loaded and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Data Load. The Data Load Wizard opens.

3. The options and steps involved depend on the DBMS type and on the selections you make. Use the following table as a guide to providing details as you pass through the pages of the wizard.
### Data Load (SQL SVR, SYB ASE)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Do you wish to initiate a new data unload operation</strong> or 'play back' a previously saved operation?</td>
<td>New Data Unload Operation - Select to define a new data unload operation. ‘Playback’ Previous Data Unload Operation - Select to use a previously defined schema extraction operation. Then in the Data Unload Definition File Name box type the location and name of the job file or click the browse button.</td>
</tr>
<tr>
<td><strong>Which database do you want to load the data into?</strong></td>
<td>Lets you click the list, and then select the server. Then click the list and select the database.</td>
</tr>
<tr>
<td><strong>Which table do you want to load the data into?</strong></td>
<td>Lets you click the list, and then select the table.</td>
</tr>
<tr>
<td><strong>Use BCP Utility</strong></td>
<td>Select to use the BCP (bulk copy program) utility.</td>
</tr>
<tr>
<td><strong>Which rows do you want to import?</strong></td>
<td>All Rows Range - Lets you type the range in the First Row and Last Row boxes.</td>
</tr>
<tr>
<td><strong>What restrictions do you want to place on the import?</strong></td>
<td><strong>Max Errors</strong> or <strong>Batch Size</strong>.</td>
</tr>
</tbody>
</table>

The following options are available against SQL Server datasources.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data File</strong></td>
<td>Lets you type the directory location of the data file or click the browse button to find the file.</td>
</tr>
<tr>
<td><strong>Format</strong></td>
<td>To use a format file, type the directory location of the format file or click the browse button to find the file.</td>
</tr>
<tr>
<td><strong>Error File</strong></td>
<td>To output errors to an error file, type the directory location of the format file or click the browse button to find the file.</td>
</tr>
<tr>
<td><strong>What character delimited the columns in the datafile?</strong></td>
<td>Lets you click the list, and then click the character.</td>
</tr>
<tr>
<td><strong>Do you wish to re-use this data load operation?</strong></td>
<td>To re-use the operation, type the location and name of the data load definition file or click the browse button to find the file. DBArtisan gives the operation a default extension of *.LOAD.</td>
</tr>
<tr>
<td><strong>Do you wish to DROP the index(es) on the target table BEFORE copying data?</strong></td>
<td>Drop Index(es) Before Loading of Data - Select to drop the indexes on the target table before copying data. Recreate Index(es) After Loading of Data - Select to recreate these indexes after the data loads.</td>
</tr>
</tbody>
</table>

The following options are available against Sybase ASE datasources.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row Terminator</strong></td>
<td>Lets you enter a value for this common BCP option.</td>
</tr>
<tr>
<td><strong>Packet Size</strong></td>
<td>Lets you enter a value for this common BCP option.</td>
</tr>
<tr>
<td><strong>Text/Image Size</strong></td>
<td>By default, Sybase ASE only copies the first 32K of data in a text or image field. To override default size, type a new size.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>Client Char Set</td>
<td>Lets you enter a value for this common BCP option.</td>
</tr>
<tr>
<td>Max Connections</td>
<td>Lets you specify the maximum connection of connections in the connection pool.</td>
</tr>
<tr>
<td>Show-fi</td>
<td>Provides the option to add columns for each functional index.</td>
</tr>
<tr>
<td>Hide-vcc</td>
<td>Provides the option to hide virtual computed columns</td>
</tr>
</tbody>
</table>

4. Review the data unload operation description to verify its accuracy. If you need to make any changes, click Back to scroll back to the appropriate panels of the wizard to make your corrections. When ready, click Execute.
Data Load (PostgreSQL)

This wizard lets you build and submit a COPY... FROM... call, copying data from a file to a table.

**Note:** For information on how to unload table data to a file suitable for loading using the Data Load utility, see Data Unload (PostgreSQL).

To load table data from a file

1. Connect to the datasource where the database to be loaded is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select **Utilities > Data Load** to open the Data Load Wizard.

3. Use the following table as a guide to performing tasks as you pass through the wizard panels:

<table>
<thead>
<tr>
<th>Step/Page</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Playback</td>
<td>New Data Load Operation</td>
<td>Select to define a new backup operation.</td>
</tr>
<tr>
<td></td>
<td>Previous Data Load Operation</td>
<td>Select to open a previously defined unload operation.</td>
</tr>
<tr>
<td>Table</td>
<td>Which database do you want to load data into and Which table do you want to load data into</td>
<td>Lets you fully qualify the database table to which data is to be loaded.</td>
</tr>
<tr>
<td>Options</td>
<td>File Name</td>
<td>Lets you provide the path and name of the file containing the data to be loaded.</td>
</tr>
<tr>
<td></td>
<td>Format</td>
<td>Lets you specify whether the data file is in text, CSV, or Binary format.</td>
</tr>
<tr>
<td></td>
<td>Encoding</td>
<td>Lets you specify either UTF8 or SQL-ASCII encoding.</td>
</tr>
<tr>
<td></td>
<td>OIDS</td>
<td>When selected, specifies copying the OID for each row.</td>
</tr>
<tr>
<td></td>
<td>Header</td>
<td>Specifies that the file contains a header line consisting of all column names.</td>
</tr>
<tr>
<td></td>
<td>Delimiter</td>
<td>The character that separates columns within each line.</td>
</tr>
<tr>
<td></td>
<td>Quote</td>
<td>Specifies the quote character for a Format of csv.</td>
</tr>
<tr>
<td></td>
<td>Escape</td>
<td>Specifies the character that should appear before a QUOTE data character value for a Format of csv.</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Null String</td>
<td>Specifies the string that represents a NULL value.</td>
<td></td>
</tr>
<tr>
<td>Columns to Import</td>
<td>Select the columns that are to be copied.</td>
<td></td>
</tr>
<tr>
<td>Save Operation</td>
<td>Do you wish to re-use this data load operation</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Lets you save the options you selected in a data load definition file.</td>
<td></td>
</tr>
<tr>
<td>Drop Index(es) BEFORE Loading of Data and</td>
<td>Lets you decide whether you want indexes dropped and specify the timing of</td>
<td></td>
</tr>
<tr>
<td>Recreate Index(es) AFTER Loading of Data</td>
<td>the DROP.</td>
<td></td>
</tr>
<tr>
<td>Summary</td>
<td>Provides a short summary of the operation options.</td>
<td></td>
</tr>
</tbody>
</table>

4. Finally, use the **Execute** button to perform the backup.
Data Pump Export (ORCL10g ^)

The Data Pump Export utility lets you build and submit a call to the expdp.exe utility to unload a dump file specifically formatted to be loaded using the impdp.exe utility. The wizard lets you specify a full set of expdp.exe parameters, which are also saved to file for convenient reuse. When ready to import, you can execute from the wizard, or independently using a command line call to expdp.exe specifying the saved parameters file.

Before using this utility:

- You must specify the location of the expdp.exe utility. For more information, see Oracle Utilities Options.
- Consult Oracle documentation for detailed information on use of the expdp.exe utility. For more information, see Accessing Third Party Documentation.
- You should also familiarize yourself with support for the Oracle Data Pump Import Utility. For details, see Data Pump Import Wizard (ORCL10g ^).

To create and execute a call to the Data Pump Export utility

1. Connect to an Oracle datasource and ensure that it is the currently selected datasource. For details, see Connected/Selected Datasource options.
2. Select Utilities > Data Pump Export to open the Data Pump Export Wizard.
3. Use the following topics as a guide to setting properties and performing tasks as you pass through the wizard panels:
   - Data Pump Export Wizard - Playback.
   - Data Pump Export Wizard - Export Data Options.
   - Data Pump Export Wizard - Object Selection.
   - Data Pump Export Wizard - Table Data Filter.
   - Data Pump Export Wizard - File and Job Settings.
   - Data Pump Export Wizard - Advanced Parameters.
   - Data Pump Export Wizard - Summary.

Finally, use the Finish button to perform the export.

Data Pump Export Wizard - Playback

When exporting a dump file set using the Data Pump Export Wizard, this panel offers the following options:
Data Pump Export Wizard - Export Data Options

This wizard page lets you work with the following parameters:

<table>
<thead>
<tr>
<th>Setting Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Export Mode</td>
<td>Lets you select a mode, specifying the dump file set content type to be exported: Tables, Schemas, Full Dump File (corresponds to FULL parameter), or Tablespaces.</td>
</tr>
<tr>
<td>Options</td>
<td>Select a Data or DDL value of ALL, DATA ONLY, or METADATA only to provide a CONTENT= parameter value, specifying the data to unload. Select a Compression value of ALL, DATA ONLY, or METADATA only to provide a COMPRESSION= parameter value, indicating what to compress before writing to the dump file set.</td>
</tr>
</tbody>
</table>

Data Pump Export Wizard - Object Selection

If you selected an Export Mode of Tables, Schemas, or Tablespaces, select the check boxes corresponding to the specific database objects to be exported.

For more general information, such as how to open this Wizard, see Data Pump Import Wizard (ORCL10g ^).

Data Pump Export Wizard - Table Data Filter

This wizard page lets you include one or more QUERY= parameters, each specifying any valid QUERY= clause, such as a WHERE clause or ORDER BY clause. For each table that is to be filtered, click in the QUERY Clause field associated with the table and type a valid clause.

Note: Use the fields in the <ALL> row to filter the list.

For more general information, such as how to open this Wizard, see Data Pump Import Wizard (ORCL10g ^).

Data Pump Export Wizard - File and Job Settings

This wizard page lets you work with the following parameters:
### Data Pump Export (ORCL10g ^)

<table>
<thead>
<tr>
<th>Setting Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dump File</strong></td>
<td><strong>Directory</strong> - Select the directory object corresponding to the file system location where the dump file is to be stored. <strong>File name</strong> - Specify the full name of the dump file. Selecting <strong>Overwrite existing dump files</strong> adds a REUSE_DUMPFILES=Y parameter, ensuring that any existing dump files are overwritten. Selecting <strong>Existing files will prevent export</strong> adds a REUSE_DUMPFILES=N parameter.</td>
</tr>
<tr>
<td><strong>Enable Logging</strong></td>
<td>If <strong>Enable Logging</strong> is unselected, a NOLOGFILE=Y parameter is included with the utility call. To enable logging, select <strong>Enable Logging</strong> and if required, overwrite the default Log File name. This includes a LOGFILE= parameter with the utility call.</td>
</tr>
<tr>
<td><strong>Job</strong></td>
<td>Lets you provide a JOBNAME= parameter value that will be included with the utility call.</td>
</tr>
</tbody>
</table>

For more general information, such as how to open this Wizard, see [Data Pump Import Wizard (ORCL10g ^)](Data Pump Import Wizard (ORCL10g ^)).

### Data Pump Export Wizard - Advanced Parameters

The Data Pump Import Wizard builds and submits a call to the `expdp.exe` utility, specifying a minimal, required set of parameters, specified on preceding pages of the wizard. The **Advanced Parameters** page lets you provide any additional parameter=value pairs supported by the utility.

**Note:** For a listing of additional, supported parameters, see [Data Pump Import/Export Parameters that can be Added Manually](Data Pump Import/Export Parameters that can be Added Manually).

- Use the **New** button to open the **Add Data Pump Parameter** dialog. Select a parameter name from the **Name** dropdown and in the **Value** box, provide the associated value.
- Use the **Edit** and **Delete** buttons to modify or remove selected parameters.

### Data Pump Export Wizard - Summary

This wizard page provides a summary of the `expdp.exe` parameters you chose on previous pages of the wizard. It also displays:

- The location of the generated parameters file (.txt).
- Instructions on how to execute the export independently of the wizard, using the parameters file

For more general information, such as how to open this Wizard, see [Data Pump Import Wizard (ORCL10g ^)](Data Pump Import Wizard (ORCL10g ^)).
Data Pump Import Wizard (ORCL10g ^)

The Data Pump Import utility lets you build and submit a call to the `impdp.exe` utility to load an `expdp.exe`-produced dump file set to a target system. The wizard lets you specify a full set of `impdp.exe` parameters, which are also saved to file for convenient reuse. When ready to import, you can execute from the wizard, or independently using a command line call to `impdp.exe` specifying the saved parameters file.

Before using this utility:

- You must specify the location of the `impdp.exe` utility. For more information, see Oracle Utilities Options.
- Consult Oracle documentation for detailed information on use of the `impdp.exe` utility. For more information, see Accessing Third Party Documentation.
- You should also familiarize yourself with support for the Oracle Data Pump Export Utility. For details, see Data Pump Export (ORCL10g ^).

To create and execute a call to the Data Pump Import utility

1. Connect to an Oracle datasource and ensure that it is the currently selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Data Pump Import to open the Data Pump Import Wizard.

3. Use the following topics as a guide to setting properties and performing tasks as you pass through the wizard panels:

   - Data Pump Import Wizard - Playback.
   - Data Pump Import Wizard - Import Data Options.
   - Data Pump Import Wizard - Object Selection.
   - Data Pump Import Wizard - Remapping.
   - Data Pump Import Wizard - Import Options.
   - Data Pump Import Wizard - Advanced Parameters.
   - Data Pump Import Wizard - Summary.

4. Finally, use the Finish button to perform the import.

Data Pump Import Wizard - Playback

When importing a dump file set using the Data Pump Import Wizard, this panel offers the following options:
Data Pump Import Wizard - Import Data Options

This wizard page lets you work with the following parameters:

<table>
<thead>
<tr>
<th>Setting Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dump File Directory</td>
<td>- Select the directory object corresponding to the file system location of the dump file. File name - Specify the full name of the dump file.</td>
</tr>
<tr>
<td>Import Mode</td>
<td>- Lets you select a mode, specifying the dump file set content type to be imported: Tables, Schemas, Full Dump File (corresponds to FULL parameter), or Tablespaces.</td>
</tr>
<tr>
<td>Options</td>
<td>- Select a Data or DDL value of ALL, DATA ONLY, or METADATA only to provide a CONTENT= parameter valuer, specifying the data to unload.</td>
</tr>
</tbody>
</table>

Data Pump Import Wizard - Object Selection

If you selected an Import Mode of Tables, Schemas, or Tablespaces, select the check boxes corresponding to the specific database objects to be imported.

Data Pump Import Wizard - Remapping

This wizard page lets you specify one or more REMAP_SCHEMA or REMAP_TABLESPACE parameters. For each source schema or tablespace that is to be remapped, click to activate the associated Target dropdown and select the target schema or tablespace.

Data Pump Import Wizard - Import Options

This wizard page lets you work with the following parameters:
Data Pump Import Wizard - Advanced Parameters

The Data Pump Import Wizard builds and submits a call to the `impdp.exe` utility, specifying a minimal, required set of parameters, specified on preceding pages of the wizard. The Advanced Parameters page lets you provide any additional parameter=value pairs supported by the utility.

**Note:** For a listing of additional, supported parameters, see Data Pump Import/Export Parameters that can be Added Manually.

- Use the New button to open the Add Data Pump Parameter dialog. Select a parameter name from the Name dropdown and in the Value box, provide the associated value.
- Use the Edit and Delete buttons to modify or remove selected parameters.

Data Pump Import Wizard - Summary

This wizard page provides a summary of the `impdp.exe` parameters you chose on previous pages of the wizard. It also displays:

- The location of the generated parameters file (.txt).
- Instructions on how to execute the import independently of the wizard, using the parameters file.
Data Unload

The Data Unload utility is available on the following platforms:

- Data Unload Wizard (DB2 LUW)
- Data Unload (SQL SVR, SYB ASE)
- Data Unload (PostgreSQL)

Data Unload Wizard (DB2 LUW)

DBArtisan offers a simple, wizard that lets you export table data. After defining the data export operation, you have the opportunity to save the job definition for future reuse.

Starting the Export Wizard

1. Connect to the datasource containing the data to be unloaded and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Data Unload. The Data Export Wizard opens.

3. The options offered depend on the selections you make. Use the following table as a guide to completing the pages of the wizard.
## Data Unload Wizard (DB2 LUW)

### Step

<table>
<thead>
<tr>
<th>New or playback action</th>
<th>Do you wish to initiate a new export operation or ‘play back’ a previously saved operation?</th>
<th>New Export Operation - Select to define a new data unload operation. Previous Export Operation - Select to use a previously defined schema extraction operation. Then in the Export Definition File Name box type the location and name of the job file or click the browse button.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datasource and format selection</td>
<td>What datasource has the data you wish to export?</td>
<td>- Lets you click the list and select the datasource. Specify the format for the data export file(s) to be generated. - Lets you click the list and select the file format. Option Button - Available if you select a delimited option. How would you like to specify the data to export? - Enter a SELECT statement. Select tables/views from a list (one export file per table/view).</td>
</tr>
<tr>
<td>SELECT statement and LOB options</td>
<td>Specify the data to be extracted from the database by entering a SELECT statement</td>
<td>- Enter the statement that will retrieve the row(s) or column(s) you want from one or more tables. Statements can be complicated. Go to <a href="http://msdn.microsoft.com/library">http://msdn.microsoft.com/library</a> and do a search on SELECT for help. Would you like to store large objects (LOBs) in separate files? - When you choose to store LOBs in separate files, you will be given the chance to store them in files outside the database tablespaces. When you choose not to store your LOBs in separate files, they will exist in a table row in the database.</td>
</tr>
<tr>
<td>Lob file details</td>
<td>If you specified that LOBs are to be stored in separate files, the following options are provided: List paths where the LOB files are to be stored - Add, Edit, or Remove files where you want LOBs to be stored. List LOB file names - Add, Edit, or Remove LOB file names.</td>
<td></td>
</tr>
<tr>
<td>Table selection details</td>
<td>Owner - Lets you select the tables and/or views you want to export or click the Check All button. Count Rows - Lets you update the table row counts. Check All - Lets you select all tables or views. Uncheck All - Lets you deselect all tables or views.</td>
<td></td>
</tr>
<tr>
<td>Output options</td>
<td>Select a directory for export files (including and LOB files) - Type the location and name of the export file or click the Browse button. Specify a path and name for the message file - Type the location and name of the message file or click the Browse button. Do you wish to re-use this data unload operation? - To re-use this data unload operation, in type the location and name of the data unload definition file or find the file by clicking the Browse button. DBArtisan writes a migrate definition file using the *.unload file extension that includes your job definition.</td>
<td></td>
</tr>
<tr>
<td>Options review</td>
<td>Review the data export operation description to verify its accuracy. If you need to make any changes, click Back to scroll back to the appropriate panels of the wizard to make your corrections.</td>
<td></td>
</tr>
</tbody>
</table>

4. When ready, click **Execute**.
Data Unload (SQL SVR, SYB ASE)

DBArtisan offers a simple, five-panel wizard that can export table data via Microsoft SQL Server’s BCP (bulk copy program) utility or Sybase ASE’s BCP (bulk copy program) utility. After defining the data export operation, you can save the job definition for future re-use.

Tip: For related information, see Data Load (SQL SVR, SYB ASE).

To unload table data

1. Connect to the datasource containing the data to be unloaded and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Data Unload. The Data Unload Wizard opens.

3. The options and steps involved depend on the DBMS type and on the selections you make. Use the following table as a guide to providing details as you pass through the pages of the wizard.

<table>
<thead>
<tr>
<th>Panel</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Do you wish to initiate a new data unload operation or ‘play back’ a previously saved operation?</td>
<td>New Data Unload Operation - Select to define a new data unload operation. ‘Playback’ Previous Data Unload Operation - Select to use a previously defined schema extraction operation. Then in the Data Unload Definition File Name box type the location and name of the job file or click the browse button.</td>
</tr>
<tr>
<td>2</td>
<td>In which directory should the unloaded files be placed?</td>
<td>Lets you specify the directory by typing the location and name of the directory or find the directory by clicking the browse button. Which database has the data you wish to unload?</td>
</tr>
<tr>
<td>3</td>
<td>The following options are available against SQL Server datasources.</td>
<td>Table Owner</td>
</tr>
</tbody>
</table>
Row Terminator    Lets you enter a value for this common BCP option.
Packet Size        Lets you enter a value for this common BCP option.
Text/Image Size    By default, Sybase only copies the first 32K of data in a text or image field. To override default size, type a new size.
Client Char Set    Lets you enter a value for this common BCP option.

4. **Do you wish to re-use this data unload operation?** To re-use this data unload operation, type the location and name of the data unload definition file or find the file by clicking the **Browse** button. DBArtisan writes a migrate definition file using the *.unload file extension that includes your job definition.

5. **Review the data unload operation description to verify its accuracy.** If you need to make any changes, click **Back** to scroll back to the appropriate panels of the wizard to make your corrections.

5. When ready, click **Execute**.
Data Unload (PostgreSQL)

This wizard lets you generate a pgadmin export data call, dumping database data to a file.

To dump database data to a file

1. Connect to the datasource where the data to be unloaded is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Data UnLoad to open the Data UnLoad Wizard.

3. Use the following table as a guide to performing tasks as you pass through the wizard panels:

<table>
<thead>
<tr>
<th>Step/Page</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Playback</td>
<td>New Data Unload Operation</td>
<td>Select to define a new unload operation.</td>
</tr>
<tr>
<td></td>
<td>Previous Data Unload Operation</td>
<td>Select to open a previously defined unload operation.</td>
</tr>
<tr>
<td>Unload Properties</td>
<td>In which directory should the unload files be placed</td>
<td>Lets you locate and select the path where the unload file will be written.</td>
</tr>
<tr>
<td></td>
<td>What datasource has the data you wish to unload</td>
<td>Lets you select the datasource that is to be unloaded.</td>
</tr>
<tr>
<td>Unload Properties</td>
<td>Use the table list to select each specific table</td>
<td>Use the table list to select each specific table that is to be unloaded.</td>
</tr>
<tr>
<td></td>
<td>that is to be unloaded.</td>
<td>The Schema dropdown can be used to reduce the number of tables displayed</td>
</tr>
<tr>
<td></td>
<td></td>
<td>to only those objects within a selected schema.</td>
</tr>
<tr>
<td>Unload Properties</td>
<td>Row Separator</td>
<td>Lets you specify whether simple linefeeds or carriage return/linefeed</td>
</tr>
<tr>
<td></td>
<td>Column separator</td>
<td>combinations are used to separate rows.</td>
</tr>
<tr>
<td></td>
<td>Quote char</td>
<td>Lets you specify whether single quote or double quotes are used for quoting.</td>
</tr>
<tr>
<td></td>
<td>Column names</td>
<td>Select this option to have the first line of the unload file contain</td>
</tr>
<tr>
<td></td>
<td>Encoding</td>
<td>column names.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Lets you specify whether you want to use simple, local character set</td>
</tr>
<tr>
<td></td>
<td></td>
<td>encoding or whether to use the Postgres-specific UTF-8 encoding.</td>
</tr>
</tbody>
</table>
Database Backup

**Quoting**
Let's specify a quoting strategy of no quoting used, quoting on string columns only, or quoting on all columns.

**Re-use**
Do you wish to re-use this data unload operation
Let's save the options you selected in a data unload definition file.

**Summary**
Provides a short summary of the operation options.

4. Finally, use the **Execute** button to perform the unload.

**Note:** The data unloaded to file can be used in a subsequent load operation. For details, see [Data Load (PostgreSQL)](##).

**Database Backup**

See the following topics for DBMS version-specific database backup wizards:

- [Database Backup (MySQL)](##)
- [Database Backup (SQL SVR)](##)
- [Database Backup (SYB ASE)](##)
- [Database Backup (PostgreSQL)](##)
Database Backup (MySQL)

The MySQL Database Backup Wizard lets you build and submit a `mysqldump` call, backing up databases to results files.

**To back up a MySQL database**

1. Connect to a MySQL datasource and ensure that it is the currently selected datasource. For details, see Connected/Selected Datasource options.
2. Select **Utilities > Database Backup** to open the Database Backup Wizard.
3. Use the following topics as a guide to setting properties and performing tasks as you pass through the wizard panels:
   - **Playback panel - Database Backup Wizard**
   - **Backup Type panel - Database Backup Wizard**
   - **Databases panel - Database Backup Wizard**
   - **Tables panel - Database Backup Wizard**
   - **Where Clause panel - Database Backup Wizard**
   - **Options panel - Database Backup Wizard**
   - **Output File Type panel - Database Backup Wizard**
   - **Normal Output File panel - Database Backup Wizard**
   - **Datafile Page panel - Database Backup Wizard**
   - **Summary panel - Database Backup Wizard**
4. Finally, use the **Finish** button to perform the backup.

For information on restoring a database from results files, see **Database Restore Wizard (MySQL)**.

**Playback panel - Database Backup Wizard**

When backing up a MySQL database, this panel offers the following options:
### Required Information

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>New Backup/Dump Operation</strong></td>
<td>This initiates the process of creating a new backup or dump operation.</td>
</tr>
<tr>
<td><strong>Enter the views SQL definition</strong></td>
<td>If you want to replay a backup operation, when you select the radio button, the browse function is enabled so you can find the .DBDump file you want to reuse.</td>
</tr>
</tbody>
</table>

### Backup Type panel - Database Backup Wizard

When backing up a MySQL database, this panel offers the following options:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Backup databases</strong></td>
<td>Lets you backup one or more entire databases.</td>
</tr>
<tr>
<td><strong>Backup tables within a single database</strong></td>
<td>Lets you backup one or more tables within a single database.</td>
</tr>
</tbody>
</table>

### Databases panel - Database Backup Wizard

When backing up a MySQL database, this panel is only available if you selected the **Backup databases** option. For details, see [Backup Type panel - Database Backup Wizard](#).

To specify the databases that are to be backed up:

1. Select each check box corresponding to the name of a database you want to back up.

### Tables panel - Database Backup Wizard

When backing up a MySQL database, this panel is only available if you selected the **Backup tables within a single database** option. For details, see [Backup Type panel - Database Backup Wizard](#).

To specify the tables that are to be backed up:

1. From the **Select tables from** list, select the database containing the tables you want to back up.
2. In the tables list, select each check box corresponding to the name of a table you want to back up.

### Where Clause panel - Database Backup Wizard

When backing up a MySQL database, this panel is only available if:

- You selected the **Backup tables within a single database** option. For details, see [Backup Type panel - Database Backup Wizard](#).
You selected a single table from the **Tables** panel. For details, see [Tables panel - Database Backup Wizard](#).

To dump only specific records

1. In the **WHERE clause** box, type a WHERE clause qualifying those records you want to dump.

**Options panel - Database Backup Wizard**

When backing up a MySQL database, this panel lets you set or select the `mysqldump` options dictating how the backup is to be performed.

**Note:** Before working with these options, consult MySQL documentation for information on the `mysqldump` program. For more information, see [Accessing Third Party Documentation](#).

The following table shows the Database Backup Wizard settings on this panel, their `mysqldump` option equivalents, and a description of their effect.
<table>
<thead>
<tr>
<th>Wizard Option</th>
<th>mysql dump Option Equivalent</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>No Data</td>
<td>--no-data</td>
<td>Table contents are not dumped</td>
</tr>
<tr>
<td>Continue if Errors Occur</td>
<td>--force</td>
<td>Continues the dump even if SQL errors occur.</td>
</tr>
<tr>
<td>Flush Server Logs</td>
<td>--flush-logs</td>
<td>Flushes server logs before starting the dump.</td>
</tr>
<tr>
<td>Drop Table Statements</td>
<td>--add-drop-table</td>
<td>Adds a DROP TABLE statement before each CREATE TABLE statement.</td>
</tr>
<tr>
<td>Lock/Unlock Statements</td>
<td>--add-locks</td>
<td>LOCK TABLE and UNLOCK TABLE statements are generated for each table dump.</td>
</tr>
<tr>
<td>Lock All Tables</td>
<td>--lock-tables</td>
<td>Locks all tables before dumping them.</td>
</tr>
<tr>
<td>Allow Keyword Column Names</td>
<td>--allow-keywords</td>
<td>Allows creation of column names that contain keywords.</td>
</tr>
<tr>
<td>Complete Insert Statements</td>
<td>--complete-insert</td>
<td>Uses complete INSERT statements, including column names.</td>
</tr>
<tr>
<td>Use MySQL Table Options</td>
<td>--create-options</td>
<td>All MySQL-specific table options are included in CREATE TABLE statements.</td>
</tr>
<tr>
<td>Use Insert Delayed Options</td>
<td>--delayed-insert</td>
<td>Writes INSERT DELAYED statements instead of INSERT statements.</td>
</tr>
<tr>
<td>Disable Keys</td>
<td>--disable-keys</td>
<td>Each INSERT statement is surrounded by disable/enable key statements.</td>
</tr>
<tr>
<td>Use Extended Inserts</td>
<td>--extended insert</td>
<td>Generates multiple-row INSERT syntax that includes several VALUES lists.</td>
</tr>
<tr>
<td>Use Create Table Statements</td>
<td>--no-create-info</td>
<td>Scripts CREATE TABLE statements for each table.</td>
</tr>
<tr>
<td>Suppress Information</td>
<td>--skip-comments</td>
<td>Additional information such as program version, server version, and host, is not written to the dump file.</td>
</tr>
<tr>
<td>Exclude Create Database Statements</td>
<td>--no-create-db</td>
<td>Suppresses CREATE DATABASE statements.</td>
</tr>
<tr>
<td>Retrieve Single Rows</td>
<td>--quick</td>
<td>Rows are retrieved one at a time.</td>
</tr>
<tr>
<td>Option</td>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Use Quotes</strong></td>
<td>--quote-names</td>
<td>Identifiers such as database, table, and column names are generated within quote characters.</td>
</tr>
<tr>
<td><strong>Use Begin Statements</strong></td>
<td>--single-transaction</td>
<td>Issues a BEGIN statement before dumping data from the server.</td>
</tr>
<tr>
<td><strong>Use First-Slave Option</strong></td>
<td>--first-slave</td>
<td>Locks all tables across all databases.</td>
</tr>
<tr>
<td><strong>Use Master-Data Option</strong></td>
<td>--master-data</td>
<td>Deselected, a CHANGE MASTER statement is written as an SQL comment.</td>
</tr>
<tr>
<td><strong>Delete Binary Logs</strong></td>
<td>--delete-master-logs</td>
<td>Deletes binary logs after the dump operation on a master replication server.</td>
</tr>
<tr>
<td><strong>Suppress Set Names Statement</strong></td>
<td>--skip-set-charset</td>
<td>Suppresses SET NAMES default_character_set statements.</td>
</tr>
<tr>
<td><strong>Default Character Set</strong></td>
<td>--default-character-set=charset</td>
<td>Uses the specified charset as the default character set.</td>
</tr>
<tr>
<td><strong>Protocol</strong></td>
<td>--protocol=</td>
<td>The connection protocol (TCP, SOCKET, PIPE, or MEMORY) to use.</td>
</tr>
<tr>
<td><strong>Max Allowed Packet</strong></td>
<td>max_allowed_packet=</td>
<td>The maximum size of the client/server communication buffer.</td>
</tr>
<tr>
<td><strong>Net Buffer Length</strong></td>
<td>net_buffer_length=</td>
<td>The initial size of the client/server communication buffer.</td>
</tr>
<tr>
<td><strong>Compress</strong></td>
<td>--compress</td>
<td>Compresses information sent between client and server if compression support is available.</td>
</tr>
<tr>
<td><strong>ANSI</strong></td>
<td>--compatible=ansi</td>
<td>These settings enable dump output compatibility modes.</td>
</tr>
<tr>
<td><strong>MySQL 3.23</strong></td>
<td>--compatible=mysql323</td>
<td></td>
</tr>
<tr>
<td><strong>MySQL 4.0</strong></td>
<td>--compatible=mysql40</td>
<td></td>
</tr>
<tr>
<td><strong>PostgresSQL</strong></td>
<td>--compatible=postgresql</td>
<td></td>
</tr>
<tr>
<td><strong>Oracle</strong></td>
<td>--compatible=oracle</td>
<td></td>
</tr>
<tr>
<td><strong>MSSQL</strong></td>
<td>--compatible=mssql</td>
<td></td>
</tr>
<tr>
<td><strong>DB2</strong></td>
<td>--compatible=db2</td>
<td></td>
</tr>
<tr>
<td><strong>MaxDB</strong></td>
<td>--compatible=maxdb</td>
<td></td>
</tr>
<tr>
<td><strong>No Key Options</strong></td>
<td>--compatible=no_key_options</td>
<td></td>
</tr>
<tr>
<td><strong>No Table Options</strong></td>
<td>--compatible=no_table_options</td>
<td></td>
</tr>
</tbody>
</table>
No Field Options

---
compatible=no_field_options

Output File Type panel - Database Backup Wizard

When backing up a MySQL database, this panel lets you select between standard output or use of the --tab option. It offers the following options:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a normal output file</td>
<td>Produces standard output.</td>
</tr>
<tr>
<td>Create a tab-separated output file</td>
<td>For each dumped table, mysqldump creates a ‘tbl_name.sql’ file that contains the CREATE TABLE statement that creates the table, and a ‘tbl_name.txt’ that contains its data.</td>
</tr>
</tbody>
</table>

For more general information, such as how to open this Wizard, see Database Restore Wizard (MySQL).

Normal Output File panel - Database Backup Wizard

When backing up a MySQL database, this panel lets you provide results file options (--result-file=file and --xml). It offers the following options:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter the path and filename of the results file</td>
<td>Lets you locate and provide/select a path and filename for the results file.</td>
</tr>
<tr>
<td>Prevent newline “\n” characters from being converted to “\r\n” carriage return/newline sequences (recommended for Windows systems)</td>
<td>Write dump output as well-formed XML</td>
</tr>
</tbody>
</table>

Datafile Page panel - Database Backup Wizard

When backing up a MySQL database, this panel is only available if

- You selected the Backup tables within a single database option. For details, see Backup Type panel - Database Backup Wizard.
- You selected the Create a tab-separated tab file option. For details, see Output File Type panel - Database Backup Wizard.

It offers the following options:
### Setting

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter the directory where the file(s) will be stored</td>
<td>Lets you provide a <code>--tab=path</code> option value.</td>
</tr>
<tr>
<td>Fields Terminated By, Fields Enclosed By, Fields Optionally Enclosed By,</td>
<td>Lets you provide <code>--fields-xxx</code> and <code>--lines--xxx</code> option values for line and column separators.</td>
</tr>
<tr>
<td>Fields Escaped By, and Lines Terminated By</td>
<td></td>
</tr>
</tbody>
</table>

### Summary panel - Database Backup Wizard

When backing up a MySQL database, this panel summarizes the choices you made in previous steps setting up the operation.
Database Backup (SQL SVR)

This wizard lets you generate a BACKUP DATABASE script to be executed immediately, scheduled, or opened in the SQL Editor.

To create a database backup

1. Connect to the datasource where the database to be backed up is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Database Backup. The Backup Wizard opens.

3. Use the following table as a guide to providing details as you pass through the pages of the wizard.

<table>
<thead>
<tr>
<th>Step/Panel</th>
<th>Options/Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Backup Operation</td>
<td>New Backup Operation Select to define a new backup operation.</td>
</tr>
<tr>
<td></td>
<td>Previous Backup Operation Select to open a previously defined backup operation and use the associated controls to provide the location and name of the job file.</td>
</tr>
<tr>
<td>Database Selection</td>
<td>Here you select the database you want to backup from a drop-down list and name the backup operation. You can keep the default name for the operation or replace it with one you type. The job description is optional and you can accept the default or write another.</td>
</tr>
<tr>
<td>Backup Type</td>
<td>Full Database Backs up the entire database. The size of the database is listed in parentheses.</td>
</tr>
<tr>
<td></td>
<td>Partial Database Generates a BACKUP DATABASE statement that includes a READ_WRITE_FILEGROUPS option, dictating a partial backup of specified files and file groups.</td>
</tr>
<tr>
<td></td>
<td>Partial Incremental Generates a BACKUP DATABASE statement that includes WITH DIFFERENTIAL and READ_WRITE_FILEGROUPS options, dictating that only specified files and file groups changed since last backup should be backed up.</td>
</tr>
<tr>
<td></td>
<td>Incremental Database Generates a BACKUP DATABASE statement that includes a WITH DIFFERENTIAL option, dictating that only potions of the database changed since last backup should be backed up.</td>
</tr>
<tr>
<td></td>
<td>File and File Group These controls are only available if the Select to specify a file or file group.</td>
</tr>
</tbody>
</table>
### Database Backup (SQL SVR)

<table>
<thead>
<tr>
<th>Transaction Log</th>
<th>Full Truncate</th>
<th>For more information, see Databases (SQL Server) - Options.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database option</td>
<td>Backs up the inactive portion of the transaction log. The size of the transaction log is listed in parentheses. <strong>With No Log</strong> (not available for SQL Server 2008 only) - Removes the inactive portion of the transaction log without making a backup of it. You should only use this command when you run out of room in the database and cannot issue DUMP TRAN WITH TRUNCATE_ONLY. <strong>Full No Truncate</strong> - Makes it possible to dump a transaction log even if the database is inaccessible. You can use this option when the data portion of your database is damaged and the transaction log resides on a separate device. <strong>With Truncate Only</strong> (not available for SQL Server 2008 only) - Removes the inactive portion of the transaction log without making a backup of it. You should use this command prior to backing up a database.</td>
<td></td>
</tr>
</tbody>
</table>

| Backup Location | This panels lets you provide values used to create a TO argument for the BACKUP DATABASE statement generated for this operation. Use the Add, Remove, and Contents buttons to manage the disk devices, tape devices, and directory/filenames that are to be specified on the TO argument. |

| Backup and Media Information | Here, you specify the backup set name, backup description, backup set password, media name, media description, and media name password. |

<table>
<thead>
<tr>
<th>Backup Options</th>
<th>Overwrite all backup sets on the device</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When selected, a WITH INIT option is generated with the BACKUP DATABASE statement, dictating that existing backup sets are to be overwritten. When deselected, a WITH NOINIT option is generated with the BACKUP DATABASE statement, dictating that this operation is appended to the media set. Selecting this option enables the Format the entire media before backup operation and Specify when the backup set can be overwritten controls.</td>
</tr>
</tbody>
</table>

| Format the entire media before backup operation | When selected, a WITH FORMAT option is generated with the BACKUP DATABASE statement, dictating that a new media set be created. When deselected, a WITH NOFORMAT option is generated with the BACKUP DATABASE statement, dictating that the existing media header and backup sets on the media volumes be preserved. |
### Specify when the backup set can be overwritten

Selecting this check box activates the **Expire Date** and **Retain Days** controls. The **Expire Date** control lets you add a WITH EXPIREDATE option to the generated BACKUP DATABASE statement, specifying when the backup set can be overwritten. The **Retain Days** control lets you add a WITH RETAINDAYS option to the generated BACKUP DATABASE statement, specifying the number of days before the backup set can be overwritten.

### Skip backup set expiration and media name checking

When selected, a WITH SKIP option is generated with the BACKUP DATABASE statement, disabling checking of expiration and name for the backup set. When deselected, a WITH NOSKIP option is generated with the BACKUP DATABASE statement, ensuring that the expiration date is checked before overwriting backup sets. This control is only enabled if **Format the entire media before backup operation** is deselected.

### Copy-Only backup

When selected, a WITH COPY-ONLY option is generated with the BACKUP DATABASE statement, specifying that this backup is a copy-only backup, with no effect on normal backup operations.

### Compression (SQL Server 2008 only)

You can select among **Use the default server setting**, **Compress** (generate a WITH COMPRESSION option), and **No Compress** (generate a WITH NO_COMPRESSION option).

### Read and verify the integrity of the backup after finish

If selected, a RESTORE VERIFYONLY is generated to follow the BACKUP DATABASE statement, verifying but not restoring the backup operation.

### Perform backup checksums

When selected, a WITH CHECKSUM option is generated with the BACKUP DATABASE statement, enabling backup checksums. When deselected, a WITH NO_CHECKSUM option is generated with the BACKUP DATABASE statement, explicitly disabling backup checksums.

### Stop on checksum error

This control is only enabled if **Perform backup checksums** is selected. When selected, a CONTINUE_AFTER_ERROR option is generated with the BACKUP DATABASE statement, ensuring that the backup will continue to run even if errors such as invalid checksums or torn pages are encountered. When deselected, a STOP_ON_ERROR option is generated with the BACKUP DATABASE statement, instructing the backup to terminate if a page checksum does not verify.

### Rewind the tape before unload

When selected, a WITH REWIND option is generated with the BACKUP DATABASE statement, forcing release and rewind of the tape. When deselected, a WITH NOREWIND option is generated with the BACKUP DATABASE statement, dictating that the tape remain open after the backup completes.
Unload the tape after backup

This control is only enabled if **Rewind the tape before unload** is selected. When selected, a **WITH UNLOAD** option is generated with the **BACKUP DATABASE** statement, forcing an unload of the tape after rewind. When selected, a **WITH NOUNLOAD** option is generated with the **BACKUP DATABASE** statement, leaving the tape loaded after the backup operation completes.

No Recovery and Standby file

These controls correspond to the mutually exclusive **STANDBY = UNDO FILE NAME** (letting you back up the tail of the log and leave the database in a read-only and standby state) and **NO RECOVERY** (letting you back up the tail of the log and leave the database in **RESTORING** state) clauses.

I/O buffers

Lets you provide a **WITH BUFFERCOUNT =** value for the **BACKUP DATABASE** statement.

Max transfer size

Lets you provide a **WITH MAXTRANSFERSIZE =** value for the **BACKUP DATABASE** statement.

Report at each

Lets you provide a **WITH STATS =** value for the **BACKUP DATABASE** statement.

Backup Operation Summary

Here you indicate whether or not you want to save the operation, and if so, where the file should be saved. Also displayed are the elements of the function you are creating. You can go back to earlier panels if you want to make changes before the job runs.

Action Selection

Open the backup script in an ISQL editor

The backup script will be opened into a new ISQL session.

**NOTE:** This option is not available for Sybase backups.

Perform the backup now

The backup will be executed immediately.

Schedule the backup for later execution

The backup will be scheduled to run at a specified date/time.

4. When ready, click **Execute**.
Database Backup (SYB ASE)

This wizard lets you generate and execute DUMP DATABASE or DUMP TRANSACTION commands.

To create a database backup

1. Connect to the datasource where the database to be backed up is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Database Backup. The Backup Wizard opens.

3. The options offered depend on the sections you make as you progress through the pages of this wizard. Use the following table as a guide to providing details as you pass through the pages of the wizard.
## Options/Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>New Backup Operation</strong></td>
<td>Select to define a new backup operation.</td>
</tr>
<tr>
<td><strong>Previous Backup Operation</strong></td>
<td>Select to open a previously defined backup operation and use the associated controls to provide the location and name of the job file.</td>
</tr>
<tr>
<td><strong>What are the source Sybase server and database?</strong></td>
<td>Select a server from the drop-down list and then the appropriate datasource.</td>
</tr>
<tr>
<td><strong>What do you want to dump?</strong></td>
<td>Database - Backs up the entire database. The size of the database is listed in parentheses. Transaction Log - Backs up the inactive portion of the transaction log. The size of the transaction log is listed in parentheses. Transaction Log With No Log - Removes the inactive portion of the transaction log without making a backup of it. You should only use this command when you run out of room in the database and cannot issue DUMP TRAN WITH TRUNCATE_ONLY. Transaction Log With Truncate Only - Removes the inactive portion of the transaction log without making a backup of it. You should use this command prior to backing up a database. Transaction Log With No Truncate - Makes it possible to dump a transaction log even if the database is inaccessible. You can use this option when the data portion of your database is damaged and the transaction log resides on a separate device.</td>
</tr>
<tr>
<td><strong>What type of dump device do you want to use?</strong></td>
<td>Choose among tape device, disk device, or file. When you select file, you need to type the file’s name.</td>
</tr>
<tr>
<td><strong>Where should messages about the dump operation be sent?</strong></td>
<td>Your options are the Operator Console, Client, or Default.</td>
</tr>
<tr>
<td><strong>Dump file</strong></td>
<td>It's up to you to specify the name of the dump file.</td>
</tr>
<tr>
<td><strong>What dump devices do you want to use?</strong></td>
<td>Lets you select from available devices.</td>
</tr>
<tr>
<td><strong>Do you want to specify any device handling options?</strong></td>
<td>Lets you provide retention time and compression level details. If you selected a tape device, rewind and dismount options are provided.</td>
</tr>
<tr>
<td><strong>Do you wish to re-use this dump operation?</strong></td>
<td>To re-use the operation, type the location and name of the definition file or click the browse button to find the file. DBArtisan gives the operation a default extension of *.dbdump.</td>
</tr>
</tbody>
</table>

4. Review the data unload operation description to verify its accuracy. If you need to make any changes, click Back to scroll back to the appropriate panels of the wizard to make your corrections. When ready, click Execute.
Database Backup (PostgreSQL)

This wizard lets you generate a pg_dump script, backing up one or more tables or views of a database.

To create a database backup

1. Connect to the datasource where the database to be backed up is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

2. Select Utilities > Database Backup to open the Backup Wizard.

3. Use the following table as a guide to performing tasks as you pass through the wizard panels:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Playback</td>
<td>New Backup Operation</td>
<td>Select to define a new backup operation.</td>
</tr>
<tr>
<td></td>
<td>Previous Backup Operation</td>
<td>Lets you specify the specific datasource and database where the tables and views to be backed up are located.</td>
</tr>
<tr>
<td>Datasource and Output Options</td>
<td>What are the datasource and database</td>
<td>Lets you specify the specific datasource and database where the tables and views to be backed up are located.</td>
</tr>
<tr>
<td></td>
<td>Specify the format for the data file(s) to be generated</td>
<td>Lets you specify a -F (--format) output format option of Custom (custom-format archive suitable for input into Database Restore utility), Plain text (plain-text SQL script file), Directory (directory-format archive suitable for input into Database Restore utility), or Tar (TAR-format archive suitable for input into Database Restore utility).</td>
</tr>
<tr>
<td></td>
<td>Compress ratio (not available if the Tar output format is selected)</td>
<td>Lets you provide a -Z option value of 0-9, specifying a pg_dump compression level.</td>
</tr>
<tr>
<td></td>
<td>Encoding</td>
<td>Lets you provide a -E option value, specifying the character set encoding of the dump file.</td>
</tr>
<tr>
<td></td>
<td>Rolename</td>
<td>Lets you provide a --role option value, instructing pg_dump to issue a SET ROLE command on connection to the database.</td>
</tr>
</tbody>
</table>
**Files**  
Specify a path for the output file to be generated and Specify a path for the message file to be generated.  
These settings let you specify the paths for the output and message files as well as the optional file that lets you reuse the current backup operation.

**Options**  
**Sections**  
Lets you provide one or more --section option values (Pre-data, Data, Post-data) specifying that the selected sections are dumped.

**Type of Objects**  
Only data - corresponds to a -a (--data-only) option, specifying that only data be dumped. Only schema - corresponds to a -s (--schema-only) option, specifying that only object definitions be dumped. Blobs - corresponds to a -b (--slobs) option, specifying that large objects be included in the dump.

**Don’t save**  
Owner- corresponds to a -O (--no-owner) option, specifying no output commands to set ownership of objects to match the original database. Privilege - corresponds to a -X (--no-privileges) option, preventing dumping of access privileges. Tablespace - corresponds to a --no-tablespaces option, specifying no output commands to select tablespaces. Unlogged table data - corresponds to a --no-unlogged-table-data option, specifying that the contents of unlogged tables are not dumped.

**Queries**  
Include CREATE DATABASE statement - corresponds to a -C (--create) option, specifying that the output begin with a command to create the database. Include DROP DATABASE statement - corresponds to a -C (--clean) option, specifying that the commands to drop objects are specified before commands to create them. Use Column Inserts - corresponds to a --column-inserts option, specifying that data is dumped as INSERT commands with explicit column names. Use Insert commands - corresponds to a --inserts option, specifying that data is dumped as INSERT commands rather than COPY.

**Disable**  
Trigger- corresponds to a --disable-triggers option, specifying that the dump include commands to temporarily disable triggers on the target tables while data is reloaded. $ quoting- corresponds to a --disable-dollar-quoting option, specifying that dollar quoting is disabled for function bodies.
### Miscellaneous

Use **SET SESSION AUTHORIZATION** - corresponds to a **--use-set-session-authorization** option, specifying that object ownership is determined using **SET SESSION AUTHORIZATION** commands instead of **ALTER OWNER** commands. With **OIDs** - corresponds to a **--oids** option, specifying that object identifiers are dumped with every table. **Verbose messages** - corresponds to a **--verbose** option, specifying that verbose mode be used. **Force double quotes on identifiers** - corresponds to a **--quote-all-identifiers** option, forcing quoting of all identifiers.

### Tables

**Select the tables and/or views to be exported**

Lets you select the tables that are to be dumped.

### Summary

Provides a short summary of the dump operation options.

4. Finally, use the **Finish** button to perform the backup.

The generated script can be used in a subsequent restore operation. For details, see [Database Restore (PostgreSQL)](Database%20Restore%20(PostgreSQL)).
Database Export (ORCL)

DBArtisan provides comprehensive graphical support for the Oracle Export Utilities. DBArtisan offers a simple wizard that guides you through the process of extracting object definitions and table data from an Oracle database and creating binary export file. DBArtisan’s Export Wizard ensures that the proper parameters and privileges are used, provides access to desired database information and resolves version compatibility differences.

The Export Wizard supports all four export modes:

- Table
- Users
- Full Database
- Point-in-time Recovery (available in Oracle8)

The benefits of using the Oracle Export Utilities range from moving data between different versions of Oracle quickly and efficiently, saving space on the database, to selectively backing up an entire or portion of a database using cumulative or incremental export functions.

**Note:** If you do not have the EXP_FULL_DATABASE role assigned to you, you may not be able to access all the functionality of the export wizard.

Starting the Database Export Wizard

1. Ensure that the path and name for the Oracle Export utility is specified in the Oracle Utilities tab of the Options Editor. For details, see Oracle Utilities Options.

2. Connect to the datasource where the database to be exported is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

3. Select Utilities > Database Export. The Data Export Wizard opens.

4. Use the topics below as a guide to providing information as you walk through the pages of the wizard:

   - Database Export Wizard - Panel 1
   - Database Export Wizard - Panel 2
   - Database Export Wizard - Panel 3
   - Database Export Wizard - Panel 4
   - Database Export Wizard - Panel 5
   - Database Export Wizard - Panel 6
5. When ready, click **Execute**.

### Database Export Wizard - Panel 1

The first panel of the Export Wizard lets you specify the source datasource, name an existing parameter file or use the existing Oracle default parameter file.

The table below describes the options and functionality on the first panel of the Data Export Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Which database has the data you wish to export?</td>
<td>Click the list, and then click the database.</td>
</tr>
<tr>
<td>Edit an existing parameter file</td>
<td>Type the location and name of the parameter file or click the browse button to find the file.</td>
</tr>
<tr>
<td>Default values</td>
<td>To use the Oracle default values for the parameter file, leave this box blank.</td>
</tr>
</tbody>
</table>

### Database Export Wizard - Panel 2

The second panel of the Export Wizard lets you select the export mode that determines the database objects you will export.

- The full database mode makes available incremental, cumulative or complete export operations.
- The point-in-time export operation can export one or more tablespaces, which you can use in an import operation to recover a tablespace at a prior point in time without affecting the rest of the database.

The table below describes the objects, related objects and structures that are exported for each mode:
Table definitions, object types defined on the table, table data by partition, nested table data, indexes defined on the table, table constraints, table permissions, column and table comments, table analysis information, triggers that refer to the table, and auditing information.

Libraries, object types, database links, sequence numbers, cluster definitions, table definitions, object types defined on the table, table data by partition, nested table data, indexes defined on the table, table constraints, table permissions, table analysis information, column and table comments, private synonyms, stored procedures, functions, packages, auditing information, views, cluster analysis information, referential constraints, triggers, snapshots, and snapshot logs.

Tablespace definitions, tablespace quotas, profiles, user definitions, roles, role privileges, system privileges, resource costs, rollback segment definitions, database links, sequence numbers, directories, libraries, object types, cluster definitions, password information, default and system auditing, object type tables, table definitions, table data by partition, nested table data, table indexes, table constraints, table privileges, table analysis information, column and table comments, auditing information, synonyms, views, stored procedures, functions, packages, triggers, cluster analysis information, snapshots, snapshot logs, refresh groups and children.

Tablespaces. (available in Oracle8)

The table below describes the options and functionality on the second panel of the Data Export Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Which mode would you like to use for this export?</td>
<td>Click the option button that corresponds to the export mode you want to implement: Table, User, Full Database, or Point-in-Time Recovery.</td>
</tr>
</tbody>
</table>

Database Export Wizard - Panel 3

The third panel of the Export Wizard lets you specify the objects you want to export based on the mode you selected in the second panel of the Export Wizard.

The table below describes the options and functionality on the third panel of the Data Export Wizard for Table mode:
Database Export (ORCL)

**Option** | **Description**
--- | ---
Select the tables and/or partitions you would like to export | To display list of available tables, click the **Owner** list, and then click the owner.

**Tables**
In the box, select the check boxes that correspond to the tables you want to export. If a table has partitions, select the check boxes that correspond the partitions you want to export. To select all tables, click the **Select All** button.

The table below describes the options and functionality on the third panel of the Data Export Wizard for User mode:

**Option** | **Description**
--- | ---
Select the users whose objects you would like to export | To display list of available users, select the check boxes that correspond to the objects you want to export. To select all objects, click the **Select All** button.

The table below describes the options and functionality on the third panel of the Data Export Wizard for Full Database mode:

**Option** | **Description**
--- | ---
Would you like to perform an incremental export | An incremental operation exports all database objects that have changed since the last incremental, cumulative, or complete export operation. NOTE: To perform an incremental export operation, you must have the `EXP_FULL_DATABASE` role. A cumulative operation exports all database objects that have changed since the last cumulative or complete export. A complete operation exports all objects.

Do you want to records this export in the system tables that track exports? | To record the export operation in the `SYS.INEXP`, `SYS.INCFIL`, and `SYS.INVID` system tables, click the **Yes** button.

The table below describes the options and functionality on the third panel of the Data Export Wizard for Point-in-Time Recovery mode:

**Option** | **Description**
--- | ---
Select the tablespaces to be recovered | To display list of available tablespaces, select the check boxes that correspond to the tablespaces you want to recover. To recover all tablespaces, click the **Select All** button.

**Database Export Wizard - Panel 4**

The fourth panel of the Export Wizard lets specify:

- The objects you want to export.
To view the progress meter.

The table below describes the options and functionality on the fourth panel of the Data Export Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check the objects you would like to export</td>
<td><strong>Note</strong>: This option is not available if you are performing a full database incremental export operation. The Oracle Export Utility automatically determines if a row has been changed since the last export operation. Select the check box that corresponds to the object(s) you want to export: To export indexes associated with the tables, select the Indexes check box. To export check constraints or referential integrity constraints, select the Constraints check box. To export object privileges, select the Grants check box. To export table data, select the Rows check box.</td>
</tr>
<tr>
<td>Rows/Dot</td>
<td>To view the progress meter which displays the status of rows being exported, in the box, type the value of the number of rows per dot you want displayed in the meter.</td>
</tr>
</tbody>
</table>

**Database Export Wizard - Panel 5**

The fifth panel of the Export Wizard lets you set the following options:

- The Export Path
- The Length of the File Record
- The Buffer Size

The table below describes the options and functionality on the fifth panel of the Data Export Wizard:
Database Export (ORCL)

Option Description
Would you like to perform a direct path export? A direct path export extracts data much faster as it bypasses the SQL Command processing layer and saves data copies whenever possible.
Would you like to accept your platform’s value for BUFSIZ as the length of the file record? Lets you select the Yes or No option button. If you clicked the No option button, in the Specify length box, type the KB value of the length. The highest value you can specify is 64 KB.
Would you like to accept your platform’s default value for the buffer size used to fetch rows? Note: This option is only valid if you are performing a conventional path export. Lets you select the Yes or No option button. If you clicked the No option button, in the Specify size box, type the KB value of the length; the highest value you can specify is 64 KB.

Database Export Wizard - Panel 6

The sixth panel of the Export Wizard lets you specify:
- Handling storage of table data.
- Type of optimizer statistics to generate when the file is imported.
- Make the data remain unchanged during the export operation.

The table below describes the options and functionality on the sixth panel of the Data Export Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Would you like table data to be consolidated into one initial extent upon import?</td>
<td>Lets you select the No or Yes option button.</td>
</tr>
<tr>
<td>What type of database optimizer statistics should be generated upon import?</td>
<td>Lets you click the appropriate option button: Estimate, Compute, or None.</td>
</tr>
<tr>
<td>Would you like to ensure that the data seen by this export operation does not change during execution?</td>
<td>Note: This option is not available for an incremental export operation. Lets you select the No or Yes option button. Click Yes to ensure that the data remains intact throughout the export operation.</td>
</tr>
</tbody>
</table>

Database Export Wizard - Panel 7

The seventh panel of the Export Wizard lets you specify names and locations for the export, parameter and logfiles.
The table below describes the options and functionality on the seventh panel of the Data Export Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supply the export file name</td>
<td>Lets you type the full location and name of the export file. Export file names use the .dmp file extension. (for example, C:\Temp\EXPBerlin.dmp). If you expect to perform the same export operation again, type the location and name of the parameter file in the corresponding box. Parameter files are stored as .txt files. (for example, C:\Temp\EXPPARBerlin.txt).</td>
</tr>
<tr>
<td>Logfile</td>
<td>To capture informational and error messages, click the option button and type the location and name of the logfile in the corresponding box. Export logfile names use the .logfile extension. (for example, C:\Temp\EXPLOGBerlin.log).</td>
</tr>
<tr>
<td>None</td>
<td>If you do not want to capture informational and error messages, click the option button.</td>
</tr>
</tbody>
</table>

**Database Export Wizard - Panel 8**

Review the data export operation description to verify its accuracy.
Database Import (ORCL)

DBArtisan provides comprehensive graphical support for the Oracle Import Utilities. DBArtisan offers a simple wizard that guides you through the process of extracting object definitions from an Oracle Export file and inputting them into the database. The Oracle Import utility only reads export files created with the Oracle Export utility. DBArtisan's Import Wizard ensures that the proper parameters and privileges are used, provides access to desired database information and resolves version compatibility differences.

The Import Wizard supports all four import modes:

- Table
- Users
- Full Database
- Point-in-time Recovery (available in Oracle8)

The Oracle Import utilities build database objects in the proper sequence to avoid dependency problems. Tables are created first, then table data is input into the proper tables, next indexes are built, then triggers are imported and finally integrity constraints are built.

**Note:** If you do not have the EXP_FULL_DATABASE role assigned to you, you may not be able to access all the functionality of the import wizard.

**Starting the Import Wizard**

1. Ensure that the path and name for the Oracle Import utility is specified in the Oracle Utilities tab of the Options Editor. For details, see Oracle Utilities Options.

2. Connect to the datasource where the database to be imported is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

3. Select Utilities > Database Import. The Data Import Wizard opens.

4. Use the topics below as a guide to providing information as you walk through the pages of the wizard:

   - Database Import Wizard - Panel 1
   - Database Import Wizard - Panel 2
   - Database Import Wizard - Panel 3
   - Database Import Wizard - Panel 4
   - Database Import Wizard - Panel 5
5. When ready, click **Execute**.

### Database Import Wizard - Panel 1

The first panel of the Import Wizard asks you to specify the target datasource and to name an existing import parameter file or use the existing Oracle default parameter file. The table below describes the options and functionality on the first panel of the Data Import Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Into which database would you like to import data?</td>
<td>Click the list, and then click the database.</td>
</tr>
<tr>
<td>Edit an existing parameter file</td>
<td>Type the location and name of the parameter file or click the browse button to find the file.</td>
</tr>
<tr>
<td>Default values</td>
<td>To use the Oracle default values for the parameter file, leave this box blank.</td>
</tr>
</tbody>
</table>

### Database Import Wizard - Panel 2

The second panel of the Import Wizard lets you specify the export file from which the data should be imported. You must also select the import mode you want to use which determines the database objects that DBArtisan imports. The table below describes the objects, related objects and structures that are imported for each mode:
The table below describes the options and functionality on the second panel of the Data Import Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the export file from which you want to import data?</td>
<td>Lets you type the location and name export file to be used in the import operation, or find the file by clicking the <strong>Browse</strong> button.</td>
</tr>
<tr>
<td>Which database was used to create this export file?</td>
<td>Lets you choose the database used for export file creation from the list.</td>
</tr>
<tr>
<td>Which mode would you like to use for this export?</td>
<td>Lets you click the option button that corresponds to the import mode you want to implement. Table User Full Database Point-In-Time</td>
</tr>
</tbody>
</table>

**Database Import Wizard - Panel 3**

The third lets you specify which objects you want to import based on the mode you selected in the second panel of the Import Wizard.

The table below describes the options and functionality on the third panel of the Data Import Wizard for Table mode:
Database Import (ORCL)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the tables and/or partitions you would like to import</td>
<td>Displays a list of available tables. Lets you click the Owner list, and then click the owner.</td>
</tr>
</tbody>
</table>

Tables
To In the box, select the check boxes that correspond to the tables you want to import. If a table has partitions, click the check boxes that correspond the partitions you want to import. To select all tables, click the Select All button.

The table below describes the options and functionality on the third panel of the Data Import Wizard for User mode:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the users whose objects you would like to import</td>
<td>To display list of available users, select the check boxes that correspond to the objects you want to import. To select all objects, click the Select All button.</td>
</tr>
</tbody>
</table>

The table below describes the options and functionality on the third panel of the Data Import Wizard for Full Database mode:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Would you like to perform an incremental import</td>
<td>An incremental operation imports all database objects that have changed since the last incremental, cumulative, or complete export operation.</td>
</tr>
</tbody>
</table>

Database Import Wizard - Panel 4

The fourth panel lets you specify options to import dependent objects, privileges and table data, and to create a file for index-creation commands.

The table below describes the options and functionality on the fourth panel of the Data Import Wizard:
Database Import (ORCL)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check the objects you would like to import</td>
<td>Select the check box that corresponds to the object(s) you want to export. To import object privileges, click the Grants check box. To import table data, select the Rows check box. To import indexes associated with the tables, select the Indexes check box.</td>
</tr>
<tr>
<td>Would you like to skip unusable indexes?</td>
<td>Lets you click the Yes or No option button.</td>
</tr>
<tr>
<td>Would you like specify a file to receive index-creation commands?</td>
<td>When this parameter is specified, index-creation commands for the requested mode are extracted and written to the specified file, rather than used to create indexes in the database. Tables and other database objects are not imported. If you clicked the Yes option button, type the location and name of the file or find the file by clicking the Browse button.</td>
</tr>
</tbody>
</table>

**Database Import Wizard - Panel 5**

The fifth panel of the Import Wizard lets you:

- Set the data rows transfer buffer size.
- Indicate if the import operation should commit after each array insert.
- Specify the option to re-use existing data files.
- Specify the option to ignore creation errors.

The table below describes the options and functionality on the fifth panel of the Data Import Wizard:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Would you like to accept your platform's default value for buffer size used to fetch rows?</td>
<td>If you select the No option button, in the Specify length box, type the KB value of the length. The highest value you can specify is 64 KB.</td>
</tr>
<tr>
<td>Should Import commit after each array insert?</td>
<td>Lets you select the No or Yes option button.</td>
</tr>
<tr>
<td>Would you like to reuse the existing datafiles making up the database?</td>
<td>Select Yes to set the reuse option in the datafile clause of the CREATE TABLESPACE command.</td>
</tr>
<tr>
<td>Should Import ignore object creation errors when attempting to create database objects?</td>
<td>Select Yes if you selected Table as your mode of import in panel 2, and the tables exist in the database in the target database.</td>
</tr>
</tbody>
</table>

**Database Import Wizard - Panel 6**

The sixth panel of the Import Wizard lets you specify:

- The length of the file record.
- How you want to implement SQL Analyze statements contained in the export file.
- To view the contents of the export file rather than import the database information.
- To view the progress meter.

The table below describes the options and functionality on the sixth panel of the Data Import Wizard:
Database Import (ORCL)

### Database Import Wizard - Panel 7

The seventh panel of the Import Wizard lets you specify names and locations for the parameter and logfiles. If you importing from an Oracle 6 export file, you can define the character set of the original file.

The table below describes the options and functionality on the seventh panel of the Data Import Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Would you like to show the contents of the export file rather than import them?</td>
<td>Lets you select the No or Yes option button.</td>
</tr>
<tr>
<td>Would you like to view the progress meter as rows are imported</td>
<td>Lets you enter the number of rows per dot displayed in the meter box, type the value of the number of rows per dot you want displayed in the meter.</td>
</tr>
<tr>
<td>Would you like to accept your platform’s value for BUFSIZ as the length of the file record?</td>
<td>If you select the No option button, in the Specify length box, type the KB value of the length; the highest value you can specify is 64 KB. <strong>Note:</strong> This option is only valid if you are performing a conventional path export. If you click the <strong>No</strong> option button, in the Specify Size box, type the KB value of the length; the highest value you can specify is 64 KB.</td>
</tr>
<tr>
<td>Would you like to accept your platform’s default value for the buffer size used to fetch rows?</td>
<td></td>
</tr>
<tr>
<td>Would you like Import to execute SQL Analyze statements found in the export file?</td>
<td>Lets you select the No or Yes option button.</td>
</tr>
</tbody>
</table>
### Database Import Wizard - Panel 8

Review the data import operation description to verify its accuracy.

**Completing Panel 8**

Review the import operation description to verify its accuracy.

1. If you need to make any changes, click **Back** to scroll back to the appropriate panels of the wizard to make your corrections.

2. If you are satisfied with the import operation, click **Execute**.

DBArtisan starts the Import operation.
Database Manager

DBArtisan lets you view and manage your databases through Database Manager. The Database Manager lets you:

- Add, modify, and delete database files.
- Add, modify, and delete transaction logfiles.
- Add or delete database options.
- View data space and transaction log usage.
- View DDL.

Opening the Database Manager

1. On the Datasource Explorer, select the Databases node. DBArtisan displays the databases.
2. In the right pane of the Explorer window, click the database link(s).
3. On the Utilities menu, select Database Manager.
Database Monitor

The Database Monitor displays all processes connected to the server. The Database Monitor:

- Lets you scan databases for potential performance problems.
- Includes tabs that provide a wealth of information about your servers.
- Color-codes each process to reflect its state and let you identify problems quickly.

Tip: You can view some Database Monitor Information by clicking the Performance node of the Datasource Navigator/Explorer.

Opening the Database Monitor

1. On the Utilities menu, select Database Monitor.

DBArtisan opens the Database Monitor.

Important Notes

- Processes and Locks are results of DB2 API calls and are not located in the system catalog tables.
- The Database Monitor may display incomplete SQL due to limitations set by the DBMS. Platforms set limitations on the values returned by the commands that gather the information.

Topics

- Color-coding
- Setting Scope Level in the Database Monitor
- Configuring the Database Monitor
- Refreshing the Database Monitor
- Database Monitor tabs
Color-coding

The Database Monitor color-codes displayed processes to reflect current state, to let you quickly spot problem conditions. For example, by default, process states are represented as follows:

<table>
<thead>
<tr>
<th>Color</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yellow</td>
<td>Sleeping or Inactive</td>
</tr>
<tr>
<td>Green</td>
<td>Running</td>
</tr>
<tr>
<td>Red</td>
<td>Blocked by another process</td>
</tr>
</tbody>
</table>

You can use the Options Editor to customize the color scheme. For details, see DB Monitor Options.

For more information, see Database Monitor.
Setting Scope Level in the Database Monitor

**Note:** The functionality is available for IBM DB2 for z/OS and OS/390 only.

The Scope list lets you specify the scope of the element being monitored in a datasharing environment. Data Sharing lets one instance of the DB2 catalog to be shared equally among all members of the group.

The Scope list is available on the Traces, Functions, Procedures, and Utilities tabs.

To set the scope level, do the following:

1. On the Database Monitor, click the target tab.
2. On the Threads, Traces, Procedures and Functions tabs:
   - In Scope, select Group for the monitoring results of all datasharing members in the set.
   - OR
     - In Scope, select Local for the monitoring results for the member that your machine is are connected to.

DBArtisan displays the results in the Database Monitor.

3. On the Utility Tab:
   - In Scope, select Group for the monitoring results of all datasharing members in the set.
   - OR
     - In Scope, select Member for data by the member name.

DBArtisan displays the results in the Database Monitor.
Refreshing the Database Monitor

As an initial default, the Database Monitor display is refreshed every 90 seconds. There are two ways to change the rate at which displayed processes on a Database Monitor tab are refreshed:

- On-the-fly, with a Database Monitor tab open, using the **Refresh Rate** control on the Database Monitor toolbar
- Setting a new initial value in the Options Editor. For details, see [DB Monitor Options](#).

1. On the Database Monitor tool bar, click the box to raise or lower the numbers, or type a new value in the box.

For more information, see [Database Monitor](#).
Configuring the Database Monitor

The Database Monitor lets you:

- Toggle to split the screen and display the target process SQL. For details, see SQL Toggle.
- Open a SQL window and display the SQL. For details, see ISQL.
- View a Query Plan for SQL running for selected processes. For details, see Query Plan.
- Save custom column-widths on a DBMS platform basis. See Customizing column widths.
- View user session details. See Session Details.

SQL Toggle

DBArtisan lets you split the Database Monitor screen and display the SQL running for selected processes.

1. On the Database Monitor tool bar, click Toggle.

Note: To open a SQL window or view a Query Plan for SQL running on selected processes, you must have your Database Monitor Screen split to display SQL on the bottom.

ISQL

DBArtisan displays the SQL running for selected processes in a SQL Editor. You must turn on the SQL Toggle to display the target SQL in the split screen. To display the SQL in a separate window do the following:

1. On the Database Monitor, click the target process.

Note: To open a SQL Editor or view a Query Plan for processes, SQL Toggle must be on, displaying the target SQL in the split screen.

2. If SQL Toggle is not on, on the Database Monitor tool bar, click Toggle.

3. On the Database Monitor tool bar, click ISQL.

DBArtisan opens a SQL window with the target process SQL.

4. To execute the SQL, click the SQL Window tool bar, click Execute.

Query Plan

The Database Monitor lets you view the Query Plan for target processes. To view the Query Plan, do the following:
Configuring the Database Monitor

1. On the Database Monitor, select the target process.

Note: To open a SQL Editor or view a Query Plan for processes, SQL Toggle must be on, displaying the target SQL in the split screen.

2. If SQL Toggle is not on, on the Database Monitor tool bar, click Toggle.

DBArtisan executes the SQL with query plan and opens a Results Editor with the results.

Customizing column widths

When you manually resize the width of a column on a Database Monitor tab, the new size is saved across startups of Database Monitor as well as DBArtisan for the current DBMS platform type.

Session Details

Note: The functionality is available for Oracle only.

The Database Monitor lets you view user session details through the User Session Information dialog. Once you open the User Session Information dialog, you can view the SQL associated with the session.

The table below describes the tabs of the User Session Information dialog:

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statistical Details</td>
<td>Lets you can scroll up and down to see parameters and values.</td>
</tr>
<tr>
<td>Waits</td>
<td>Displays either historic or current wait statistics and lets you display or filter out idle wait events. NOTE: Data returned for historic session waits is different than the data returned for current session waits.</td>
</tr>
<tr>
<td>Current SQL</td>
<td>Lets you view the SQL for this session.</td>
</tr>
</tbody>
</table>

Completing the Session Details Dialog Box

1. On the Database Monitor tool bar, click Session.

DBArtisan opens the User Session Information dialog.

2. On the Statistical Details tab, in the Session Parameters grid, you can scroll up and down to see parameters and values.

3. On the Waits tab, view select Historical Waits or Current Waits.

4. Select Include Idle Waits to display idle wait events.

5. On the Current SQL tab, view the SQL for this session.
6. When you finish viewing SQL, click **OK**.

DBArtisan returns to the **Database Monitor** dialog.

## Database Monitor tabs

The following table describes the tabs available on the Database Monitor.

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Processes</td>
<td>The Database Monitor <strong>Processes</strong> tab displays all processes connected to the server and lets you scan databases for potential performance problems, view each process for potential performance problems, and view login time and seconds idle since last call. For more information, see <a href="#">Killing Processes</a>.</td>
</tr>
<tr>
<td>Long Operations (ORCL)</td>
<td>Displays statistics from the Oracle $V$SESSION$<em>$LONGOPS view or calculated from those base statistics. The primary criterion for an operation's inclusion in the $V$SESSION$</em>$LONGOPS view is that the operation runs for more than six seconds. There are additional criteria for inclusion in the $V$SESSION$<em>$LOGOPS view, including type of operation. Before working with this functionality, you should be familiar with the Oracle $V$SESSION$</em>$LONGOPS view. For information on using Oracle documentation, see <a href="#">Accessing Third Party Documentation</a>. The following columns are available for each operation listed on this tab: <strong>SID</strong> - The session identifier (SID), <strong>START TIME</strong> - The start time of the operation (START_TIME), <strong>TIME REMAINING</strong> - Estimated number of seconds before the operation completes (TIME_REMAINING), <strong>PERCENT COMPLETE</strong> - Completion status, expressed as a percentage (SOFAR / TOTALWORK) * 100), <strong>UNITS SO FAR</strong> - The units of work currently completed (SOFAR), <strong>TOTAL WORK</strong> - The total units of work for the operation (TOTALWORK), <strong>UNIT OF MEASUREMENT</strong> - The units of measurement (UNITS), <strong>ELAPSED SECOND</strong> - The number of seconds since the operation started (ELAPSED_SECONDS), <strong>MESSAGE</strong> - A statistics summary message (MESSAGE), <strong>SERIAL #</strong> - The Session serial number (SERIAL#), <strong>OPERATION NAME</strong> - A description of the operation (OPNAME), <strong>TARGET OBJECT</strong> - The object that the operation is carried out against (TARGET), <strong>TARGET DESCRIPTION</strong> - A description of the target object (TARGET_DESC), <strong>LAST UPDATE TIME</strong> - The time when statistics were last updated (LAST_UPDATE_TIME), <strong>CONTEXT</strong> - An application-provided value (CONTEXT), <strong>USERNAME</strong> - The identifier of the user executing the operation (USERNAME).</td>
</tr>
<tr>
<td>Threads (DB2 z/OS)</td>
<td>Displays the threads on the target datasource. For related information, see <a href="#">Setting Scope Level in the Database Monitor</a>.</td>
</tr>
<tr>
<td>Locks</td>
<td>Displays all processes that are currently holding locks on an IBM DB2 database. Locks include: <strong>Shared Lock</strong> - A Shared Lock lets other users view and read objects concurrently. The Shared Lock owner or other concurrent processes cannot alter data in tablespaces, tables, or partitions. <strong>Exclusive Lock</strong> - DBArtisan promotes locks from Shared to Exclusive when a user decides to update an object. Once DBArtisan promotes the lock, the user must complete the update before the lock can return to shared mode; another user cannot demote a shared lock. Exclusive locks exclude other users from viewing updates before they are committed. There can only be one exclusive lock for a set of objects. The first thread gets the exclusive lock and holds it until the update is committed. Once the update is committed, the exclusive lock returns to shared mode. <strong>You cannot update a lock in DBArtisan.</strong></td>
</tr>
</tbody>
</table>
## Database Monitor tabs

### Utilities (DB2 z/OS)
Displays wizards that are typically run from the command line and do not apply to a particular type of schema object. Some of these wizards are also available via the command menus for objects. The wizards include Check Data, Check Index, Copy to Copy, Load Java, Merge Copy, Modify Recovery, Modify Statistics, Rebuild Index (DB2 z/OS), Reorganize /Reorg, Reorg (DB2 z/OS Tablespace), Runstats Index, Runstats Tablespace, Unload, and Maintain Template. To run a wizard, select the command in the right pane of the application and click the **Execute** button on the Datasource Explorer toolbar. For related information, see Setting Scope Level in the Database Monitor.

### Procedures (DB2 z/OS)
Displays the procedures on the target datasource. For related information, see Setting Scope Level in the Database Monitor.

### Functions (DB2 z/OS)
Displays the functions on the target datasource. For related information, see Setting Scope Level in the Database Monitor.

### Traces (DB2 z/OS)
Displays the traces on the target datasource.

### Logs (DB2 z/OS)
Displays the logs on the target datasource.

### Bufferpools
Displays the bufferpools on the target datasource.

### All Locks (DB2 z/OS)
Displays all processes that are currently holding locks on a database.

### Blocking Locks
Displays the locks that are blocked. Detect blocking locks as they occur, as they can escalate into dead lock situations which can force you to shut down and restart your server to clear the traffic.

### Active Rollback Segment
Rollback or undo segments are used to guarantee transactional integrity. When a transaction has not been committed or rolled back, a rollback segment will be in use with live transactional data. The Active Rollback Segment tab displays information concerning active rollback segments.

### Data Dictionary Cache
Displays key indicators in determining the performance of the shared pool. It shows how often object definitions are found in memory vs. having to read them in from disk. Because Oracle references the data dictionary many times when an SQL statement is processed, it is imperative that as much of this vital reference information be kept in RAM as possible.

### Datafile I/O
Displays details concerning the physical I/O activity at the datafile level. Physical I/O consists of Oracle going to disk to gather or write data. Logical I/O refers to data access performed in memory. The database writer (DBWR) and log writer (LGWR) processes typically perform all the I/O work in the database against the physical datafile used to hold information. The checkpoint and archive processes (CKPT and ARCH), also perform I/O work in the database.

### General Statistics
Displays general statistics data, including names and values.

### Hit Ratio By User
The database server reads and updates all data from a bufferpool because memory access is much faster than disk access. Data is copied from disk to a bufferpool as needed by the applications using the database. When the server needs to read/write data and the data is already in the bufferpool, no disk access is required. However, if
the data is not in the bufferpool, it needs to be read from the disk, which is significantly slower process. The buffer pool hit ratio indicates the percentage of time that the database server did not need to load a page to service the request for a page.

Latches

Latches protect many memory structures in Oracle's SGA. They ensure that one and only one process at a time can run or modify any memory structure at the same instant. Much more restrictive than locks (which at least allow for some collective user interaction), latches have no queuing mechanism so either you get it or you do not and are forced to continually retry.

Library Cache

The library cache holds commonly used SQL statements - basically database code objects. A method for improving performance in Oracle is to encourage the reuse of SQL statements so expensive parse operations may be avoided. The library cache assists this tuning effort.

MTS Dispatcher Contention

Displays Microsoft Transaction Server data. DBArtisan lets you develop and deploy COM-based applications using Microsoft Transaction Server.

MTS Server Contention

Displays Microsoft Transaction Server data. DBArtisan lets you develop and deploy COM-based applications using Microsoft Transaction Server.

Open Cursors

Open cursors consume Oracle resources and have the potential to degrade performance, especially if the SQL code being used in the cursor is inefficient. The Open Cursors tab lets you quickly spot user accounts that have many cursors opened as well as the actual performance statistics for each opened cursor.

Parallel Queries

Displays the total number of queries eligible to be run in parallel.

SGA Detail

The Oracle System Global Area (SGA) is Oracle's memory structural area devoted to facilitating the transfer of data and information between clients and the Oracle database.

SGA Hit Ratios

The Oracle System Global Area (SGA) is Oracle's memory structural area devoted to facilitating the transfer of data and information between clients and the Oracle database.

SGA Summary

The Oracle System Global Area (SGA) is Oracle's memory structural area devoted to facilitating the transfer of data and information between clients and the Oracle database.

Tablespace I/O

Displays details concerning the physical I/O activity at the tablespace level. Physical I/O consists of Oracle going to disk to gather or write data. Logical I/O refers to data access performed in memory. The database writer (DBWR) and log writer (LGWR) processes typically perform all the I/O work in the database. Other processes like the checkpoint and archive processes (CKPT and ARCH) may also be used.

System I/O Summary (SQL SVR)

Displays a summary of I/O activities that occur at the system level.

Database I/O Summary (SQL SVR)

Displays an overview of I/O operations at the database level.
Database Monitor tabs

User I/O Summary (SQL SVR) Displays an overview of I/O operations at the user operation level.

Waits (SQL SVR) Displays a detailed view of all wait activity occurring on the server.

Top SQL Cache (SQL SVR) Displays the top 100 objects in the SQL cache, ranked by use counts.

Last 50 Backups (SQL SVR) Displays the last fifty backups performed by the Microsoft SQL Server and lets you reference hot backup details at the server level within DBArtisan.

File I/O Summary (SQL SVR) Displays an overview of I/O operations at the database file level.

Top Twenty SQL (ORCL) Lets you view the Top Twenty SQL, the top (worst) SQL running in the Oracle shared pool. For more information, see SQL Toggle, Query Plan, and iSQL.

Wait Events (ORCL) Lets you analyze bottlenecks and discover what a database is waiting on.

Prepared Transactions (PSTGRS) The Database Monitor Prepared Transactions tab displays identification details for transactions that have been prepared for two-phase commit. The following pg_prepared_xacts table columns are displayed for each transaction: transaction ID, global ID, date and time that the PREPARE TRANSACTION statement was executed, and the owner and database associated with the transaction.

When this tab is active, the toolbar lets you Commit and Rollback a selected transaction.
Killing Processes

If you have system administrator privileges, DBArtisan lets you kill processes from the Database Monitor.

1. On the Utilities menu, select Database Monitor.

DBArtisan opens the Database Monitor.

2. Click the target process to kill.

3. On the Database Monitor toolbar, click Kill.

4. Click Yes.

DBArtisan confirms you want to kill the process and closes the DBArtisan message.

Topics

- Configuring the Database Monitor.

Database Recover/Restore

Recover/Restore utilities are available for the following DBMS platforms:

- Database Restore (SQL SVR)
- Database Restore (SYB ASE)
- Database Restore Wizard (MySQL)
- Database Restore (PostgreSQL)
Database Restore (SQL SVR)

This Wizard lets you build and submit a RESTORE statement, selecting a restore type as well as other options.

To restore from backup

1. Connect to the datasource where the database to be restored is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

3. Use the topics below as a guide to providing information as you walk through the pages of the wizard:
   - Playback or New Operation
   - Database Selection
   - Recovery Completion
   - Backup and Media Set Information
   - Recovery Options
   - Recover Operation Summary
   - Action Selection

4. When ready, click Finish.
Database Restore (SQL SVR)

Playback or New Operation

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Recovery/Load Operation</td>
<td>This initiates the process of creating a new recovery operation.</td>
</tr>
<tr>
<td>Previous Recovery/Load Operation</td>
<td>If you want to replay a recovery operation, when you select the radio button, the browse function is enabled so you can find the .sqrc file you want to reuse.</td>
</tr>
</tbody>
</table>

Database Selection

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Database</td>
<td>From the drop-down list, specify the target database for the recovery.</td>
</tr>
<tr>
<td>Restore Type</td>
<td>Elect to restore the database, filegroups or files, or a transaction log.</td>
</tr>
<tr>
<td>Backup Source</td>
<td>From Backup History - Find backup sets between the dates you specify and make your selection. From Device - Specify the device. Click Add or Edit to open the Recovery Wizard. Or, click Remove or Remove All to eliminate the device(s) from this operation.</td>
</tr>
</tbody>
</table>

Recovery Completion

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leave database operational</td>
<td>No more transaction logs can be recovered.</td>
</tr>
<tr>
<td>Leave database non-operational</td>
<td>You can restore more transaction logs.</td>
</tr>
<tr>
<td>Leave database read-only</td>
<td>You can restore more transaction logs.</td>
</tr>
<tr>
<td>Force restore over existing database</td>
<td></td>
</tr>
<tr>
<td>Eject tapes (if any) after restoring each backup</td>
<td>Eject tapes after the backup is restored.</td>
</tr>
<tr>
<td>Point in time restore</td>
<td>Select the date and time from which you want the restore operation to take place.</td>
</tr>
</tbody>
</table>

Backup and Media Set Information

Here, for MS SQL, you specify the backup set name, backup set password, media name, and media name password. Any existing backup files are listed.

If you are creating at Leave database read-only operation, the Undo File option is enabled. Browse to find the file you want to undo.
Recovery Options

For MS SQL, the backup file is identified here, and if you are creating a new database from another database’s backup, you can rename files in the Recover As box.

For Sybase ASE, you see the default backup file, which you can easily change. You also have the option, for tape device operations, to load the data with decompression.

Recover Operation Summary

You can elect to save the recovery operation. You can see the default location where the recovery operation will be saved or you can browse to another location. The summary panel displays the choices you have made to this point. Go back to make changes.

Action Selection

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open the recovery script in an ISQL editor</td>
<td>The recovery script will be opened into a new ISQL session. NOTE: This option is not available for Sybase ASE recoveries.</td>
</tr>
<tr>
<td>Perform the recovery now</td>
<td>The recovery will be executed immediately.</td>
</tr>
<tr>
<td>Schedule the recovery for later execution</td>
<td>The recovery will be scheduled to run at a specified date/time.</td>
</tr>
</tbody>
</table>
Database Restore (SYB ASE)

This wizard lets you generate and submit a LOAD DATABASE statement, restoring a database and logs from tape, disk, or file.

To restore from backup

1. Connect to the datasource where the database to be restored is located and ensure that it is the selected datasource. For details, see Connected/Selected Datasource options.

3. Use the topics below as a guide to providing information as you walk through the pages of the wizard:
   - Playback or New Operation
   - Database Selection for Sybase ASE
   - Recovery Completion for Sybase ASE
   - Dump Device Selection for Sybase ASE
   - Tape Handling Options for Sybase ASE
   - Recovery Options
   - Recover Operation Summary
   - Action Selection

4. When ready, click Finish.

Playback or New Operation

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Recovery/Load Operation</td>
<td>This initiates the process of creating a new recovery operation.</td>
</tr>
<tr>
<td>Previous Recovery/Load</td>
<td>If you want to replay a recovery operation, when you select the radio button, the browse function is enabled so you can find the .sqrc file you want to reuse.</td>
</tr>
<tr>
<td>Operation</td>
<td></td>
</tr>
</tbody>
</table>

Database Selection for Sybase ASE

Here you select the Sybase server and database you want to recover from the dropdown lists.
Recovery Completion for Sybase ASE

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Which operation do you want to perform?</td>
<td>Load Database - Specifies that the complete database and transaction log should be restored. Load Transaction Log - Specifies that only the transaction log should be applied to the database. List Database - Validates a load database operation without actually performing the load. List Transaction Log - Validates a load transaction operation without actually performing the load.</td>
</tr>
<tr>
<td>Information type you want to see</td>
<td>Header Only, Brief Description, or Detailed Description.</td>
</tr>
<tr>
<td>If you are loading or listing a transaction log...</td>
<td>If you are loading the transaction log, in the If you are loading or listing a transaction log... box, type the specific log time you want to load.</td>
</tr>
</tbody>
</table>

Backup and Media Information for Sybase ASE

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>What type of dump device do you want to use?</td>
<td>Choose among: Tape or Disk Device: Existing options for either of these choices become apparent on the next panel. If none are available, you won’t see any devices. File: You must type the name of the file you want use</td>
</tr>
<tr>
<td>Where should messages about the load operation be sent?</td>
<td>Select among: Default, Client, or Console.</td>
</tr>
<tr>
<td>Dump File</td>
<td>You must type the name of the file where you want to send the load operation messages.</td>
</tr>
</tbody>
</table>

Dump Device Selection for Sybase ASE

If you elected to use a tape or disk device, here you select which specific tape/disk device you want to use. You can choose one or more of the devices that appear in the panel. If none appear, you have to go Back to pick another device type. You can specify tape or disk properties by clicking each device, and then clicking the Attributes button. If you click Attribute, the Device Attribute Editor dialog opens.

Tape Handling Options for Sybase ASE

You can opt to dismount after the operation completes or rewind and unload after the operation completes.
Recovery Options

For MS SQL, the backup file is identified here, and if you are creating a new database from another database’s backup, you can rename files in the Recover As box.

For Sybase ASE, you see the default backup file, which you can easily change. You also have the option, for tape device operations, to load the data with decompression.

Recover Operation Summary

You can elect to save the recovery operation. You can see the default location where the recovery operation will be saved or you can browse to another location. The summary panel displays the choices you have made to this point. Go back to make changes.

Action Selection

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open the recovery script in an ISQL editor</td>
<td>The recovery script will be opened into a new ISQL session. NOTE: This option is not available for Sybase ASE recoveries.</td>
</tr>
<tr>
<td>Perform the recovery now</td>
<td>The recovery will be executed immediately.</td>
</tr>
<tr>
<td>Schedule the recovery for later execution</td>
<td>The recovery will be scheduled to run at a specified date/time.</td>
</tr>
</tbody>
</table>
Database Restore Wizard (MySQL)

The MySQL Database Restore Wizard lets you build and submit a `mysqlimport` call, restoring a database from the data files generated by the Database Backup utility. For information on backing up a MySQL database, see Database Backup (MySQL).

To restore a MySQL database

1. Connect to a MySQL datasource and ensure that it is the currently selected datasource. For details, see Connected/Selected Datasource options.
2. Select Utilities > Database Restore to open the Database Import Wizard.
3. Use the following topics as a guide to setting properties and performing tasks as you pass through the wizard panels:

   - **Playback** panel - for details, see Playback panel - Database Import Wizard.
   - **Target Database** panel - for details, see Target Database panel - Database Import Wizard.
   - **Select Datafiles** panel - for details, see Select Data Files panel - Database Import Wizard.
   - **Options** panel - for details, see Options panel - Database Import Wizard.
   - **Duplicate Key Options** panel - for details, see Duplicate Key Options panel - Database Import Wizard.
   - **Summary** panel - for details, see Summary panel - Database Import Wizard.
4. Finally, use the Finish button to perform the restore.

Playback panel - Database Import Wizard

When restoring a MySQL database, this panel offers the following options:
Database Restore Wizard (MySQL)

Required Information

**New Database Import Operation**
- This initiates the process of creating a new restore operation.

**Enter the views SQL definition**
- If you want to replay a restore operation, when you select the radio button, the browse function is enabled so you can find the .DBImport file you want to reuse.

Target Database panel - Database Import Wizard

When restoring a MySQL database, this panel lets you specify the database to be restored.

To set the database that is to be restored
- Select a database from the Please choose the target database list.

Select Data Files panel - Database Import Wizard

When restoring a MySQL database, this panel lets you build a list of dumped results files that are to be used to restore the database.

To set up a list of result files
- Use the New button to add a new entry to the list, and then use the browse button to locate and select a results file.
- Use the Delete button to remove a selected file from the list.
- Use the arrow buttons to change the position of a selected file in the list.

Options panel - Database Import Wizard

When restoring up a MySQL database, this panel lets you set or select the mysqlimport options dictating how the backup is to be performed.

**Note:** Before working with these options, consult MySQL documentation for information on the mysqlimport program. For more information, see Accessing Third Party Documentation.

The following table shows the Database Backup Wizard settings on this panel, their mysqldump option equivalents, and a description of their effect.
<table>
<thead>
<tr>
<th>Wizard Option</th>
<th>mysql!dump Option Equivalent</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocol</td>
<td>--protocol=</td>
<td>Select the communication protocol (TCP, SOCKET, PIPE, or MEMORY) to be used for communication between client and server.</td>
</tr>
<tr>
<td>Compress</td>
<td>--compress</td>
<td>Compresses all information sent between the client and server.</td>
</tr>
<tr>
<td>Delete Table Data</td>
<td>--delete</td>
<td>Empties the table before importing from the results file.</td>
</tr>
<tr>
<td>Force Continue</td>
<td>--force</td>
<td>Force the restore to continue even if SQL errors occur.</td>
</tr>
<tr>
<td>Lock Tables</td>
<td>--lock-tables</td>
<td>Locks all tables for writing before processing results files.</td>
</tr>
<tr>
<td>Input File Location</td>
<td>--local</td>
<td>Indicate whether the results file is on the server (SERVER) or client (LOCAL).</td>
</tr>
<tr>
<td>Ignore Header Rows</td>
<td>--ignore-lines=</td>
<td>Indicate the number of rows at the start of the file that are to be ignored.</td>
</tr>
<tr>
<td>Fields Terminated By, Fields Enclosed By, Fields Optionally Enclosed By, Fields Escaped By, and Lines Terminated By</td>
<td>Let you provide --fields... and --lines--terminated-by option values for line and column separators.</td>
<td></td>
</tr>
</tbody>
</table>

**Duplicate Key Options panel - Database Import Wizard**

When restoring up a MySQL database, this panel lets you manage handling of input rows that duplicate existing rows on unique key values.

To specify duplicate row handling, select one of the following options:

- Select **New Rows Replace Existing Rows** (\--replace equivalent)
- Select **Ignore Input Rows That Duplicate Existing Rows** (\--ignore equivalent)
- Select **Allow An Error To Occur When Duplicate Is Found And Ignore The Rest Of The Input File** (equivalent to mysqlimport execution with neither \--replace or \--ignore options)

**Summary panel - Database Import Wizard**

When restoring up a MySQL database, this panel summarizes the choices you made in previous steps setting up the operation.
Database Restore (PostgreSQL)

This wizard lets you generate and submit a pg_restore utility operation, restoring one or more tables or views of a database from a previous backup.

Note: For information on generating a pg_dump backup script, see [Database Backup (PostgreSQL)](PostgreSQL).

To restore a database from backup

1. Connect to the datasource where the database to be restored is located and ensure that it is the currently selected datasource. For details, see [Connected/Selected Datasource options](PostgreSQL).

2. Select Utilities > Database Restore to open the Restore Wizard.

3. Use the following table as a guide to performing tasks as you pass through the wizard panels:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Playback</td>
<td>New Backup Operation</td>
<td>Select to define a new backup operation.</td>
</tr>
<tr>
<td></td>
<td>Previous Backup Operation</td>
<td>Lets you specify a previously saved operation.</td>
</tr>
<tr>
<td>Datasource and Input options</td>
<td>What are the destination datasource and database</td>
<td>Lets you specify the specific datasource and database where the tables and views in the backup script are to be restored.</td>
</tr>
<tr>
<td></td>
<td>Specify the format for the data file(s) to be generated</td>
<td>Lets you specify a -F (--format) archive format option of Custom or Tar or Directory.</td>
</tr>
<tr>
<td></td>
<td>Number of jobs</td>
<td>Lets you provide a --j (--jobs) option value, specifying that the most time-consuming parts of the restore run as separate, concurrent jobs.</td>
</tr>
<tr>
<td></td>
<td>Rolename</td>
<td>Lets you provide a --role option value, specify the role used to perform the restore.</td>
</tr>
</tbody>
</table>
### Database Restore (PostgreSQL)

#### Files

Specify the data input file to be restored. Specify a path for the message file to be generated, and Do you wish to re-use this restore operation?

These settings lets you select the archive file used for the restore, specify the paths for the message file, and specify the path for the optional file that lets you reuse the current backup operation.

#### Options

**Sections**

Lets you provide one or more --section option values (Pre-data, Data, Post-data) specifying that the selected sections are restored.

**Type of Objects**

Only data - corresponds to a -a (--data-only) option, specifying that only data be restored. Only schema - corresponds to a -s (--schema-only) option, specifying that only object definitions be restored.

**Don't save**

Owner- corresponds to a -O (--no-owner) option, specifying no output commands to set ownership of objects to match the original database. Privilege - corresponds to a -X (--no-privileges) option, preventing restoration of access privileges. Tablespace - corresponds to a --no-tablespaces) option, specifying no output commands to select tablespaces.

**Queries**

Include CREATE DATABASE statement - corresponds to a -C (--create) option, specifying that the database be created before restoring into it. Clean before restore - corresponds to a -C (--clean) option, specifying that the commands to drop objects are specified before commands to create them. Use Column Inserts - corresponds to a --column-inserts option, specifying that data is dumped as INSERT commands with explicit column names. Single transaction - corresponds to a -1 (--single-transaction) option, specifying that the restore be executed as a single transaction.

**Miscellaneous**

Use SET SESSION AUTHORIZATION - corresponds to a --use-set-session-authorization option, specifying that object ownership is determined using SET SESSION AUTHORIZATION commands instead of ALTER OWNER commands. Exit on error - corresponds to a --exit-on-error option, specifying that the restore is aborted if an error is encountered. Verbose messages - corresponds to a --verbose option, specifying that verbose mode be used.
**Objects**
Use the object list to select each specific object that is to be restored. The Schema dropdown can be used to reduce the number of objects displayed to only those objects within a selected schema.

**Summary**
Provides a short summary of the dump operation options.

4. Finally, use the **Finish** button to perform the backup.
Free Space Deficit (ORCL)

One of the central tasks of every Oracle administrator is to monitor the availability of free space in tablespaces. When a data segment (e.g., table, index or cluster) is created on a tablespace, it acquires an initial extent of a determined size. As it grows, the data segment will eventually need to acquire another extent to store additional data. If a data segment cannot acquire its next extent, all further transactions on it will fail.

The Free Space Deficit Monitor identifies any objects that will not be able to acquire their next extent. Whenever it identifies a problem data segment, you should take corrective action as soon as possible. To address the problem, you can:

1. Reduce the object’s Next Extent Size from the appropriate Object Editor.
2. Increase the availability of free space in the tablespace by:
   - Adding datafiles.
   - Activating autoextend for the tablespace’s datafiles. Autoextend allows the datafiles to grow to fill available room on the physical drive. This option is only available with Oracle.

The table below describes the objects:

<table>
<thead>
<tr>
<th>Category</th>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace</td>
<td>Name</td>
<td>Name of the tablespace.</td>
</tr>
<tr>
<td></td>
<td>Largest Free Section</td>
<td>Largest contiguous section of free space in a tablespace.</td>
</tr>
<tr>
<td>Objects</td>
<td>Object Name</td>
<td>Name of any object that will not be able to acquire its next extent because it will be larger than the Largest Free Section.</td>
</tr>
<tr>
<td></td>
<td>Object Type</td>
<td>Type of the object, such as a table, index or cluster, that will not be able to acquire its next extent.</td>
</tr>
<tr>
<td></td>
<td>Next Extent</td>
<td>Specified size of the object’s next extent. One of the options you have to correct the problem is to reduce the next extent size so that it is smaller than the Largest Free Section.</td>
</tr>
</tbody>
</table>

Opening the Free Space Deficit Dialog Box

1. On the Utilities menu, select Free Space Deficit.

DBArtisan opens the Free Space Deficit dialog.

The table below describes the options and functionality on the Free Space Deficit dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>Lets you click the owner for whom you want to analyze free space.</td>
</tr>
</tbody>
</table>
Instance Configuration

To let you configure and tune your database(s), DBArtisan offers a utility that lets you view and edit the configuration parameters for each server. These configuration parameters are stored in the system catalog and used when restarting the server. For detailed information on the meaning and purpose of each server configuration parameter, see the System Administration Guide and Performance and Tuning Guide.

**Note:** Many changes to instance configuration parameters require you to shutdown and to restart the server before the changes take effect.

1. On the **Datasources** menu, select **Configure**.
2. To modify a parameter, double-click the parameter or click **Edit**.

DBArtisan opens the **Edit Configuration** dialog.

**Note:** To modify a parameter, the parameter must have a Yes in the Session Modifiable or System Modifiable column of the Instance Parameter grid.

The table below describes the options and functionality on the **Edit Configuration** dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Value</td>
<td>Lets you type the value for the parameter.</td>
</tr>
</tbody>
</table>
Instance Parameter Configuration (ORCL)

DBArtisan lets you configure and tune your Oracle databases. DBArtisan offers a utility that lets you view and edit the settings for each Oracle instance. DBArtisan derives its information from the system catalog. To reconfigure your Oracle instance, you must edit the parameter settings in the applicable configuration file (for example, INITORCL.ORA).

**Note:** After changing the settings, shut down and restart the database server for the changes to take effect.

**Changing an Instance Parameter**
1. On the **Datasources** menu, select **Configure**. DBArtisan opens the **Instance Parameters** dialog.
2. To modify an instance parameter, double-click the target instance parameter or click the **Edit** button to open the **Edit Configuration** dialog.

**Note:** To modify an instance parameter, the parameter must have a Yes in the Session Modifiable or System Modifiable column of the Instance Parameter grid.

The table below describes the options and functionality on the **Edit Configuration** dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Value</td>
<td>Lets you type the value for the parameter.</td>
</tr>
</tbody>
</table>

**Extracting Instance Configuration Parameters**
DBArtisan lets you extract the statements for setting and displaying your instance configuration parameters.

1. On the Explorer, select the **Configuration** node.
DBArtisan displays the parameters in the right pane of the Datasource Explorer.
2. In the right pane of the Explorer, click the target parameter(s).
3. On the Explorer toolbar, click **Extract**.

OR

In the right-pane of the Explorer, right-click the parameters, and then click **Extract**. DBArtisan extracts the definition to a text window.
Generating a Report on Configuration Parameters

DBArtisan lets you generate a detailed report containing information about your instance configuration parameters. The reports derive their contents from the information displayed in the right hand side of the Datasource Explorer. To facilitate the online publication of these reports, DBArtisan generates the report in Hypertext Mark-Up Language (HTML). You can view the report directly in DBArtisan’s built-in HTML-browser.

Note: For more information on generating reports, see Schema Publication.

1. On the Explorer, select the Configuration node.

DBArtisan displays the parameters in the right pane of the Datasource Explorer.

2. In the right pane of the Explorer, click the target parameter(s).

OR

In the right-pane of the Explorer, right-click the parameters, and then click Report.

DBArtisan opens the Report dialog.

The table below describes the options and functionality on the Report dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report Home Page File Name</td>
<td>To change the report home page file name, in the box, type the location and name of the file or find the file by clicking the Browse icon.</td>
</tr>
<tr>
<td>Report Title</td>
<td>To change the report title, in the box, type the location and name of the file or click the Browse button to find the file.</td>
</tr>
</tbody>
</table>
Maximum Extent Limits (ORCL)

When an object reaches its maximum extent limit, it cannot acquire any new free space. This can cause critical problems in a production database. DBArtisan’s Maximum Extent Limits for Oracle tool lets you quickly find and correct space problems.

Opening the Maximum Extent Limits Dialog Box

1. On the Utilities menu, select Maximum Extent Limits.

DBArtisan opens the Maximum Extent Limits dialog.

The table below describes the options and functionality on Maximum Extent Limits dialog.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Owner</td>
<td>Lets you select owner of the objects to display the Objects box.</td>
</tr>
<tr>
<td>Objects</td>
<td>Objects for the user account(s) that have reached their maximum extent limit.</td>
</tr>
<tr>
<td>Edit Button</td>
<td>To increase an object’s maximum extent limit, edit the object and adjust its maximum extent property to a higher value or to unlimited.</td>
</tr>
</tbody>
</table>
Pinned Code (ORCL)

For Oracle, DBArtisan now offers a Pinned Code Utility that lets you pin or unpin code objects in memory. This ensures that frequently accessed database stored procedures, triggers, functions, etc., are available in memory, which improves their overall execution performance.

**Note:** To create the DBMS_SHARED_POOL package log on as SYS and run the DBMSPOOL.SQL script that is found in the ORACLE_HOME\RDBMS\ADMIN directory.

Opening the Pin Code Dialog Box

1. On the **Utilities** menu, select **Pinned Code**.

DBArtisan opens the **Pin Code** dialog.

The table below describes the options and functionality on **Pin Code** dialog.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User</td>
<td>Lets you select the object user.</td>
</tr>
<tr>
<td>Pin Button</td>
<td>To pin an object, select the target object, and then click the <strong>Pin</strong> button.</td>
</tr>
<tr>
<td>UnPin Button</td>
<td>To unpin an object, select the target object, and then click the <strong>UnPin</strong> button.</td>
</tr>
<tr>
<td>Flush SGA Button</td>
<td>Click to flush the Oracle shared pool to remove fragmentation and any unwanted code objects from memory.</td>
</tr>
</tbody>
</table>

You must install the SYS.DBMS_SHARED_POOL package on your Oracle server to use this utility.

Confirm Shared Pool Flush

The **Confirmed Shared Pool Flush** dialog lets you confirm that you want to flush the Shared Pool. Flushing the Shared Pool causes all non-pinned code objects to be removed. After you flush the Shared Pool, all non-pinned objects are parsed and reloaded back into the pool on the next execution. This can extend first-time execution response times.
Resource Cost (ORCL)

When you create a profile, you can assign a composite resource limit to it. The composite limit is a weighted average of four individual resource limits:

- Connect time
- Private SGA
- CPU per session
- Logical reads per session

The default setting is to weight each of these measures equally. You can alter the weights by issuing an ALTER RESOURCE COST command. DBArtisan provides a visual interface for constructing such a command.

**Altering Resource Cost**

1. On the **Utilities** menu, select **Alter Resource Cost**.

DBArtisan opens the **Alter Resource Cost** dialog.

The table below describes the options and functionality on the **Alter Resource Cost** dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weightings</td>
<td>In the box, specify the weightings for each resource limit by typing the weight value in the corresponding box: <strong>Connect time</strong>, <strong>Private SGA</strong>, <strong>CPU per session</strong>, or <strong>Logical reads per session</strong>.</td>
</tr>
<tr>
<td>Enable Resource Limits</td>
<td>Select to To enable the resource limit changes immediately.</td>
</tr>
</tbody>
</table>

---

Embarcadero Technologies
Resource Limits (SYB ASE)

Resource limits are sets of parameters that let you maximize your datasource assets. By setting resource limits, you can prevent transactions and queries from congesting server resources. This ensures that you do not:

- Exceed estimated or actual input/output demands determined by the optimizer.
- Return a number of rows beyond a set limit.
- Exceed a defined elapsed time.

DBArtisan includes the **Resource Limits** dialog that lets you perform the following tasks:

- Showing Resource Limits
- Adding Resource Limits
- Editing Resource Limits
- Dropping Resource Limits

Opening the Resource Limits Dialog Box

You must connect to a datasource running Sybase ASE before you can open the **Resource Limits** dialog. To open the **Resource Limits** dialog, do the following:

1. On the Datasource Navigator/Explorer, select the target datasource node.
2. On the Utilities menu, select **Resource Limits**.

DBArtisan opens the **Resource Limits** dialog.

The table below describes the columns in the Resource Limits table of the **Resource Limits** dialog.
### Resource Limits (SYB ASE)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The login name for the resource limit.</td>
</tr>
<tr>
<td>appname</td>
<td>The application for the resource limit.</td>
</tr>
<tr>
<td>rangename</td>
<td>The time range in which the resource limit is enforced. The time range is a contiguous block of time.</td>
</tr>
<tr>
<td>rangeid</td>
<td>The value of the rangename.</td>
</tr>
<tr>
<td>limitid</td>
<td>The value and type of the resource limit.</td>
</tr>
<tr>
<td>limitvalue</td>
<td>The value of the resource limit.</td>
</tr>
<tr>
<td>enforced</td>
<td>The value and enforcement time for the resource limit.</td>
</tr>
<tr>
<td>action</td>
<td>The code number of the action for the resource limit. The codes numbers are: 1=Issue a warning 2=Abort the query batch 3=Abort the transaction 4=Kill the session</td>
</tr>
<tr>
<td>scope</td>
<td>The code number of the scope for the resource limit. The codes numbers are: 1=Query 2=Query batch 4=Transaction 6=Batch and transaction</td>
</tr>
</tbody>
</table>

### Showing Resource Limits

DBArtisan displays all resource limits for the current datasource. In addition, DBArtisan lets you use the Resource Limits dialog to search for and display specific resource limits. In the Resource Limits dialog, you can specify search criteria for resource limits. DBArtisan displays the resource limits that meet your search criteria in the Resource Limits table of the Resource Limits dialog.

### Displaying Resource Limits

1. On the Datasource Navigator/Explorer, select the target datasource node.
2. On the Utilities menu, select Resource Limits.

DBArtisan opens the Resource Limits dialog.

3. Specify the search parameters. The table below describes the search parameters in the Resource Limits dialog:
### Resource Limits (SYB ASE)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Login list</td>
<td>Lets you specify the target login or logins.</td>
</tr>
<tr>
<td>Application list</td>
<td>Lets you specify an application or applications for the limit criteria.</td>
</tr>
<tr>
<td>Limit Time check box</td>
<td>Lets you specify a time range in which to enforce the resource limit.</td>
</tr>
<tr>
<td>Limit Time list</td>
<td>Lets you specify a start time for the resource limit. The start time must be within the proceeding 24 hours. To specify the start time, you must select the Limit Time check box.</td>
</tr>
<tr>
<td>Limit Day list</td>
<td>Lets you specify the day or day(s) for the resource limit.</td>
</tr>
<tr>
<td>Scope list</td>
<td>Lets you specify the scope of the target action(s). On the Scope list, the numbers next to each scope display in the scope column of the Resource Limits table.</td>
</tr>
<tr>
<td>Action list</td>
<td>Lets you specify the action to take place when a resource limit is exceeded. On the Action list, the numbers next to each action display in the action column of the Resource Limits table.</td>
</tr>
</tbody>
</table>

4. When you finish specifying search parameters, click **List Limits**.

DBArtisan lists the resource limits meeting the target criteria in the Resource Limits table.

**Tip:** To sort the display of the Resource Limits list, click a column heading.

## Adding Resource Limits

DBArtisan offers a simple graphical wizard that guides you through the process of creating a resource limit without requiring you to know any of the underlying commands.

1. On the Datasource Navigator/Explorer, select the target datasource node.
2. On the **Utilities** menu, select **Resource Limits**.

DBArtisan opens the **Resource Limits** dialog.

3. In the **Resource Limits** dialog, click **Add**.

DBArtisan opens the **Resource Limit Wizard - Panel 1**

### Resource Limit Wizard - Panel 1

The first panel of the Resource Limit Wizard lets you identify the objects to which the resource limit will apply.

The table below describes the options and functionality on the first panel of the Resource Limit Wizard:
Option | Description
--- | ---
Add Button | Click to open the [Add/Edit Resource Limit Object Dialog Box](#).  
Edit Button | Click to open the [Add/Edit Resource Limit Object Dialog Box](#).

Add/Edit Resource Limit Object Dialog Box

The table below describes the options and functionality on the Add/Edit Resource Limit Object dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| Login | Lets you click the list, and then click the target user login.  
Application | Click the list, and then click the target application.

Resource Limit Wizard - Panel 2

The second panel of the Resource Limit Wizard lets you specify:

- The type of resource limit.
- The value of the resource limit type.
- The time during which the limit will be enforced.

The table below describes the options and functionality on the second panel of the Resource Limit Wizard:
Resource Limits (SYB ASE)

Option | Description
--- | ---
Select the type of resource limit | Lets you specify the type of resource limit by clicking one of the following option buttons: **Input/output cost**, **Elapsed time**, or **Row count**.

Limit Value box | Note: You must type the value for the limit to continue.

Time Range | Lets you click the list, and then click the target named range.

Modify, Add, and Edit buttons | Click to add or edit a named time range. DBArtisan opens the [Named Time Ranges Dialog Box](#).

Pre-execution | To specify the execution times during which the limit will be enforced, select the target check box(es):

Execution | To specify the execution times during which the limit will be enforced, select the target check box(es):

**Named Time Ranges Dialog Box**

A time range is a contiguous set of days. For example if you designate a Friday start day and a Monday end day, the time range includes the weekend.

The table below describes the options and functionality on the **Named Time Ranges** dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>In the box, type a name for the new time range.</td>
</tr>
<tr>
<td>Start time</td>
<td>In the box, specify the start time.</td>
</tr>
<tr>
<td>End time</td>
<td>In the box, specify the end time.</td>
</tr>
<tr>
<td>Start day</td>
<td>In the box, specify the beginning of the time range.</td>
</tr>
<tr>
<td>End day</td>
<td>In the box, specify the end of the time range.</td>
</tr>
</tbody>
</table>

**Resource Limit Wizard - Panel 3**

The third panel of the Resource Limit Wizard lets you specify the scope of the resource limit and the action to perform when the limit is exceeded. The available scopes are dependent on the type of resource limit you selected on the previous panel of the wizard.

The table below describes the types and available scopes:
Resource Limit Type  Available Scope

Input/output cost  Query
Elapsed time  Query batch, Transaction, and Query batch and transaction
Row count  Query

The table below describes the options and functionality on the third panel of the Resource Limit Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Click one of the option buttons to specify the scope of the resource limit: Query, Query batch, Transaction, Query batch and transaction</td>
</tr>
<tr>
<td>Action</td>
<td>Click one the following option buttons to specify the action to take when the resource limit is exceeded: Issue a warning, Abort the query batch, Abort the transaction, or Kill the session</td>
</tr>
</tbody>
</table>

**Resource Limit Wizard - Last Panel**

The last panel of the Resource Limit Wizard lets you:

- Preview the SQL for function that adds the resource limit.
- Execute the SQL for function that adds the resource limit.

**Completing the Last Panel**

1. Review the SQL.
2. Click **Execute**.

**Editing Resource Limits**

DBArtisan lets you edit resource limits. To edit resource limits, do the following:

1. On the Datasource Navigator/Explorer, select the target datasource node.
2. On the **Utilities** menu, select **Resource Limits**.

DBArtisan opens the **Resource Limits** dialog.

3. In the Resource Limits grid, select the target resource limit.
4. Click **Edit**.

DBArtisan opens the Resource Limit Editor.

5. To modify the limit value, in the Limit Value box edit the value.
6. To change the type of action, click a different option button.
7. Click **OK**.

**Dropping Resource Limits**

DBArtisan lets you drop resource limits. To drop resource limits, do the following:

1. On the Datasource Navigator/Explorer, select the target datasource node.
2. On the **Utilities** menu, select **Resource Limits**.

DBArtisan opens the **Resource Limits** dialog.

3. In the Resource Limits grid, select the target resource limit.
4. Click **Drop**.

DBArtisan opens a confirm drop message.

5. Click **Yes**.
Schema Extraction and Migration

DBArtisan lets you migrate schema and table data between databases on the same or different servers. Similarly, you can build and store a schema extraction script. Both features employ a wizard that walks you through the process and make use of similar options.

For detailed information, see the following topics:

- Using the Schema Extraction Wizard
- Using the Schema Migration Wizard
- Common Schema Migration and Extraction Options
- Migration and Object Restrictions/requirements
Using the Schema Extraction Wizard

The Schema Extraction wizard walks you through the process of building an extraction script, executing it for storage of the database or object schema in a file. The basic process includes choosing the server and database objects for extractions and specifying options that dictate how the extraction script is built. This utility allows you to:

- Extract and archive entire databases or sets of database objects.
- Generate the complete definition of any database object type.
- Reverse-engineer schema, and also place the SQL statements in their proper sequence, regardless of the objects you select.
- Create a new schema extraction operation.
- Reuse a previously defined schema extraction operation.
- Specify the target object types to extract.
- Specify the dependent object types automatically extracted for any object type.
- Set the general script type and options.
- Preview the definition of your schema extraction operation.

Platform Availability

DB2 LUW DB2 z/OS ITB/FBD * ORCL PSTGRS * SQL SVR SYB ASE SYB IQ
✓ ✓ ✓ ✓ ✓ ✓ ✓

To build and execute a schema extraction script

1. Connect to the datasource where you want to extract schema. For details, see Connecting to Datasources.

2. On the Datasource Navigator/Explorer select the target database or database object.

4. Use the following table as a guide to understanding and setting options in the wizard:
### Using the Schema Extraction Wizard

<table>
<thead>
<tr>
<th>Panel</th>
<th>Tasks and Settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Playback</td>
<td><strong>Perform new extraction</strong> and <strong>Playback an existing extraction</strong></td>
<td>Lets you start a new extraction or select an existing extraction script you want to replay from the drop-down list. NOTE: When the script opens, you can make changes to the operation you are replaying. The changes you make will overwrite the current script.</td>
</tr>
<tr>
<td>Connection</td>
<td><strong>Source Datasource</strong></td>
<td>Lets you select the datasource from which you want to extract schema.</td>
</tr>
<tr>
<td>Catalogs (only displayed for multiple database DBMS datasources)</td>
<td><strong>Source Database</strong></td>
<td>Lets you select one or more databases from which you want to extract schema.</td>
</tr>
<tr>
<td>Object Selection</td>
<td><strong>Schemas</strong></td>
<td>Opens a dialog that lets you narrow the choice of candidate objects by selecting only those associated with specified schema.</td>
</tr>
<tr>
<td></td>
<td><strong>Object Types</strong></td>
<td>Lets you select the object types that will be extracted. You can use the expand/collapse icons to hide and show the dependent object types for each object. As you select object types, all objects of that type (that satisfy the Schemas criteria) are made available for selection in the Objects list. Selected dependent object types are also made available in the Objects list. For information on setting the dependent object type automatically selected to be extracted along with each object type, see DDL Extract Options.</td>
</tr>
<tr>
<td></td>
<td><strong>Objects</strong></td>
<td>Lets you select the specific objects that will be extracted. For each object selected, you can also select the specific dependent objects that are to be extracted.</td>
</tr>
<tr>
<td>Options</td>
<td><strong>Example Preview</strong></td>
<td>This panel lets you choose migration/extraction options and view an Example Preview script that is updated as you choose options. It also lets you save your options choices as a template, with an option to use the saved template as the default. For a detailed descriptions of the options presented on this panel, see Common Schema Migration and Extraction Options.</td>
</tr>
<tr>
<td>Summary</td>
<td><strong>Output script to file</strong></td>
<td>Lets you output the script performing the extraction to a file with the specified path and name.</td>
</tr>
<tr>
<td></td>
<td><strong>Save existing operation</strong></td>
<td>Lets you save a copy the choices you made on the wizard panels. On subsequent schema extractions, you can then playback the existing extraction, optionally changing option settings, in creating an extraction script. You specify the path and name of the file in which to save the extraction operation.</td>
</tr>
</tbody>
</table>
Click **Finish** when ready to proceed with the extraction.

**Execute**
Displays the status of the extraction with details on the number of objects retrieved, the number of errors detected, and the elapsed time. On completion, the schema definition is stored in the file you specified on the previous panel. Filter options (Show All, Show Errors, and Show Warnings) let you display specific types of messages generated during the extraction process. When the extraction completes, you can also use the following options:

**Continue**
Opens the extraction script in the ISQL Editor. For more information, see Coding Environments/Editors.

**Report**
Opens a detailed report on the results of the schema extraction.
Using the Schema Migration Wizard

DBArtisan offers robust cross-DBMS-platform object migration capabilities that can migrate schema and table data between databases on the same or different servers. DBArtisan’s migration capabilities automatically resolve differences between DBMS platforms, alleviating the responsibility of knowing the syntax and object variations inherent in database platforms. The Schema Migration Wizard sequences the creation of objects in the proper order to eliminate dependency errors. It also has the intelligence to use the fastest method available for copying table data.

The Schema Migration Wizard lets you:

- Create a new schema migration operation.
- Re-use a previously defined schema migration operation.
- Specify a source and a target datasource.
- Specify server object types, database object types, and general migration options.
- Select specific objects and to set certain migration options for each object type.
- Specify the dependent object types automatically migrated for any object type.
- Specify object ownership.
- Specify if the migration operation is to be saved for reuse.

**Caution:** Schema migration jobs created in earlier versions of DBArtisan that were saved with a .migrate file extension must be re-created in DBArtisan 8.1 or later. Only migration jobs with a .sav extension can be reused.

The table below describes the object types that can be migrated to different supported platforms and the utility used to accomplish the migration operation:

<table>
<thead>
<tr>
<th>Source</th>
<th>Target</th>
<th>Object Type</th>
<th>Data Out Method</th>
<th>Data In Method</th>

</tbody>
</table>

To copy objects between servers, the Schema Migration Wizard establishes separate connections to both the source and target servers. Based on the copy options you choose, it then migrates schema from the source to the target database. If the bulk copy command is used when copying table data, a temporary BCP file is built in the temp directory of your computer.

**Note:** Before migrating, ensure that any object requirements, restrictions, or restrictions are satisfied. For details, see [Migration and Object Restrictions/requirements](#).

**To Open the Schema Migration Wizard**

1. Connect to the datasource from which you want to migrate schema. For details, see [Connecting to Datasources](#).
2. On the Datasource Navigator/Explorer, select the target database or database object.
3. On the **Utilities** menu, select **Schema Migration**.

The Migration Wizard opens.
Using the Schema Migration Wizard

4. Use the following table as a guide to understanding and setting options in the wizard:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Tasks and Settings</th>
<th>Description</th>

</tr>
</tbody>
</table>
Using the Schema Migration Wizard

Save existing operation

Lets you save a copy the choices you made on the wizard panels. On subsequent schema migrations, you can then playback the saved migration settings, optionally changing option settings. You specify the path and name of the file in which to save the migration operation.

Click **Finish** when ready to proceed with the extraction.

**Execute**

Displays the status of the migration with details on the number of objects retrieved and created, the number of errors detected, and the elapsed time. Filter options (Show All, Show Errors, and Show Warnings) let you display specific types of messages generated during the migration process. When the extraction completes, you can also use the following option:

**Continue**

Opens the extraction script in the ISQL Editor. For more information, see [Coding Environments/Editors](#).

**Report**

Opens a detailed report on the results of the schema migration.

**Topics**

- [Executing Statements Before or After Creation of Functions or Procedures](#)
Executing Statements Before or After Creation of Functions or Procedures

During migration, it can be necessary to have statements executed before and after creation of the procedure or function. This can be useful for example, if you need to create or drop temporary tables used by the function or procedure. DBArtisan supports the use of two tag pairs, ETStart and ETEnd, that let you embed statements in the first comment block of a stored procedure or function. The following shows the expected syntax:

```sql
create procedure dbo.procname(@a numeric) as
/*
<ETStart> SQL Statement </ETStart>
<ETEnd> SQL Statement </ETEnd>
*/
begin
...
```
Common Schema Migration and Extraction Options

When extracting or migrating schema, the wizards present a set of options that let you specify how the extraction or migration script is created. The following table describes these options.

Note: Depending on the DBMS you are working with, the types of objects you choose to migrate/extract, and the specific migration or extraction operation, not all options are available.

<table>
<thead>
<tr>
<th>Tasks and Settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group Dependencies</td>
<td>If set to True, objects that are dependent on each other are placed together in the script. For example, Table A would be followed by all objects dependent on Table A. If set to False, all objects of the same type are extracted simultaneously.</td>
</tr>
<tr>
<td>Script... options</td>
<td>Depending on the DBMS you working with and the types of objects you selected, these options let you specify whether you want to include Create statements, Drop statements, System Privileges, Object Privileges, and If Not Exists statements in the script.</td>
</tr>
<tr>
<td>Script Owner</td>
<td>True/False to include the owner in the scripts or not.</td>
</tr>
<tr>
<td>Owner</td>
<td>Retain Owner/Change Owner</td>
</tr>
<tr>
<td>Change Owner To</td>
<td>If you opted to change the owner, choose the new owner to use when scripting options from the drop-down list.</td>
</tr>
<tr>
<td>Copy Owner</td>
<td>Lets you retain the owner in the extraction/migration.</td>
</tr>
<tr>
<td>Overwrite Existing</td>
<td>Choose one of the following options: Overwrite Existing: objects are overwritten with no prompt. Objects on the target datasource are dropped before new objects are created Prompt Whether To Overwrite: The user will be prompted before the object is dropped and re-created. (Note: this will be done on an object-by-object basis). Do Not Overwrite Existing: If the object exists on the target datasource, no attempts is made to recreate it on the target. Ignore Overwrite: (default) Artisan will try to create the migrated objects, without checking the existence on the target datasource.</td>
</tr>
<tr>
<td>Generate Script</td>
<td>If set to FALSE, the generated DDL is executed on the target datasource. If set to TRUE, DArtisan generates a script which could be used to migrate the schema at a later date.</td>
</tr>
</tbody>
</table>

Topics

- Using the Schema Extraction Wizard
Migration and Object Restrictions/requirements

Some objects have additional requirements, exceptions, or options. Before migrating a database object, check your database platform for additional information:

- Migrating IBM DB2 for Windows/Unix Objects
- Migrating IBM DB2 for OS/390 and z/OS Objects
- Migrating Microsoft SQL Server Objects
- Migrating Oracle Objects
- Migrating Sybase ASE Objects
Migrating IBM DB2 for Windows/Unix Objects

The table describes the condition(s) that need to be satisfied on the target database to migrate objects:

<table>
<thead>
<tr>
<th>Object</th>
<th>Condition(s) on Target Database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aliases</td>
<td>The login must already exist on the target server. The user must already exist in the target database.</td>
</tr>
<tr>
<td>Indexes</td>
<td>The base tables must already exist in the target database.</td>
</tr>
<tr>
<td>Nodegroups</td>
<td>The base tables must already exist in the target database.</td>

</tbody>
</table>
Migrating Sybase ASE Objects

The table describes the condition(s) that need to be satisfied on the target database to migrate objects:

<table>
<thead>
<tr>
<th>Object</th>
<th>Condition(s) on Target Database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aliases</td>
<td>The login must already exist on the target server. The user must already exist in the target database.</td>
</tr>
<tr>
<td>Defaults</td>
<td>The owner of the default must exist in the target database. Any bound user datatypes must exist in the target database. Any bound table columns must exist in the target database.</td>
</tr>
<tr>
<td>Groups</td>
<td>To migrate any object privileges granted to groups, the database objects must already exist in the target database.</td>
</tr>
<tr>
<td>Procedures</td>
<td>The user who owns the procedure(s) must already exist in the target database. Any objects referenced by the procedure(s) must already exist in the target database.</td>
</tr>
<tr>
<td>Remote Servers</td>
<td>DBArtisan lets you migrate the schema for one or more remote servers between cross-platform DBMSs. Specifically, you can migrate remote servers between different versions of Sybase ASE and Microsoft SQL Servers.</td>
</tr>
<tr>
<td>Roles</td>
<td>To migrate any object privileges granted to roles, the database objects must already exist in the target database.</td>
</tr>
</tbody>
</table>
Migrating Sybase ASE Objects

Rules
The owner of the rule must exist in the target database. Any bound user datatypes must exist in the target database. Any bound table columns must exist in the target database.

Segments
To migrate segments successfully, all referenced database fragments must already exist in the target database.

Tables
Any referenced user datatypes must already exist in the target database. If you are copying segment placement also, then the segments must already exist in the target database. Any defaults referenced by the table must already exist in the target database. Any rules referenced by the table must already exist in the target database. If the tables have foreign key references to tables not included in the migration, these tables must already exist in the target database. NOTE: DBArtisan no longer changes the table lock scheme from ALLPAGES back to DATAROWS on the target server when using BCP.exe version dated after December 1997.

Triggers
The base tables and their owners must already exist in the target database. Any objects referenced by the trigger, including other tables, views and other stored procedures, must already exist in the target database.

User Datatypes
The owner of the user datatype must exist in the target database. Any bound defaults and rules must exist in the target database.

Users
The logins must already exist in the target server. The database objects must already exist in the target database.

Views
Any objects referenced by the view, including tables and other views, must already exist in the target database. The owner of the view must already exist in the target database.
Schema Publication

The Schema Publication Wizard lets you generate HTML reports documenting the details of your schema, databases, and objects, which you can share over an intranet or the Internet. DBArtisan uses HTML Templates to create the reports which you can manually edit to create customized reports.

Schema publication produces a two-pane report. The left-hand pane lets you navigate through all objects contained in the report while the right-hand pane shows details for an individual object. The following example shows a report on three Microsoft SQL Server default objects, displaying details for a default named `UTDS.DefaultObject`.

The Schema Publication Wizard lets you:

- Generate reports for all or any level of your database.
- View, find, and print the HTML reports directly in DBArtisan with the built-in HTML browser.
- Create a new schema publication operation.
- Re-use a previously defined schema publication operation.
- Select a datasource for which you want to generate an HTML report.
- Select the server object type and database object type for which you want to publish a schema report and lets you customize the report.
- Select specific objects and to set certain script options for each object type.
- Specify the report directory, HTML file name, and report title.
Save the schema publication operation for re-use.

Preview the definition of your schema publication operation.

**Platform Availability**

*DB2 LUW*  
*DB2 z/OS*  
*ITB/FBD*  
*ORCL*  
*PSTGRS*  
*SQL SVR*  
*SYB ASE*  
*SYB IQ*  

To create a schema report

1. Connect to the datasource for which you want to produce a schema report. For details, see Connecting to Datasources.

2. On the **Utilities** menu, select **Schema Publication**.

3. Use the following table as a guide to understanding and setting options in the wizard:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Tasks and Settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Playback</td>
<td>Perform new publication</td>
<td>Select to define a new schema publication operation.</td>
</tr>
<tr>
<td></td>
<td>Playback an existing publication</td>
<td>Lets you enable use of a previously defined publication operation and provide the path and file name of the operation.</td>
</tr>
<tr>
<td>Connection</td>
<td></td>
<td>Lets you select the datasource to be published.</td>
</tr>
<tr>
<td>Catalogs</td>
<td></td>
<td>Lets you select the target database.</td>
</tr>
<tr>
<td>(SQL Server, MySQL, and Sybase ASE datasources only)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Object Selection</td>
<td>Schemas</td>
<td>Opens a dialog that lets you narrow the choice of candidate objects by selecting only those associated with specified schema.</td>
</tr>
<tr>
<td></td>
<td>Object Types</td>
<td>Lets you select the object types and database object types that will be published.</td>
</tr>
<tr>
<td></td>
<td>Objects</td>
<td>As you select types from the <strong>Object Types</strong> list, an entry corresponding to that type is added to the <strong>Objects</strong> list. To publish only specific objects of that type, expand the list for that type and select the check boxes corresponding to the objects you want to publish.</td>
</tr>
</tbody>
</table>

Summary

This panel presents a visual summary of your selections and offers the following options:

**Output script to file**

Lets you specify the name and path of a file to store the output script.

**Save existing operation**

Lets you save a copy the choices you made on the wizard panels. On subsequent publications, you can then playback the saved settings, optionally changing specific option settings. You specify the path and name of the file in which to save the migration operation.

**Append date and timestamp to output file name** and **Save output file in date specific folders**

Lets you store and name output files using time and date elements.

Click **Finish** when ready to proceed with the extraction.

**Execute**

Displays a real-time status of the operation and a summary of the results.
Session Information (ORCL)

Oracle tracks detailed information about the resources used by each session on a database. This information is useful for analyzing resource utilization patterns between user sessions to monitor performance.

The information displayed is derived from the Oracle system tables, SYS.V_$STATNAME and SYS.V_$SESSTAT. Consult the Oracle documentation or detailed descriptions in the meanings of each session parameter.

Tip: Waits lets you analyze bottlenecks and discover what a database is waiting on.

Viewing Session Information

1. On the Utilities menu, select Session Information.

DBArtisan opens the User Session Information dialog.

2. Complete the User Session Information Dialog Box.

3. When you finish viewing SQL, click Close to return to the User Session Information dialog.

4. When you finish viewing the session information, click Close.
SQL Logfile

You can instruct DBArtisan to log all of its SQL statements to a file so that you have an audit trail of application activity. The SQL Logfile captures all the SQL sent by the DBArtisan to populate its editors or to execute your commands. You can use this logfile not only to audit application activity, but also to build SQL scripts for querying system catalogs.

Activating SQL Logging

1. On the Logfile menu, select Log SQL.

Opening the Logfile

1. On the Logfile menu, select Open. DBArtisan opens the SQL Logfile into an SQL window.

Logfile Options

You can open the Options Editor from the Logfile menu option and make any changes to your logging options. For details, see Logging Options.

Truncating the Logfile

If the SQL Logfile is growing too large, you can flush it directly from the main menu.

1. On the Logfile menu, select Truncate. DBArtisan deletes the contents of the SQL Logfile.
Top Sessions (ORCL)

Being able to identify the top resource users in an Oracle system is a valuable tuning asset. The Top Sessions Options Dialog Boxlets you quickly pinpoint the heaviest users of I/O and memory usage. The Top Sessions utility quickly finds and ranks user sessions based on their resource usage.

Opening the Top Sessions Dialog Box

1. On the Utilities menu, select Top Sessions.

DBArtisan opens the Top Sessions dialog.

The table below describes the options and functionality on the Top Sessions dialog.

Tip: Click the Options button to open the Top Sessions Options Dialog Box.

Top Sessions Options Dialog Box

The table below describes the options and functionality on the Top Sessions Options dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>
Project support

Database project management facilities help you organize, alter, and keep track of changes to database objects or SQL scripts. The project management facilities act as a repository to maintain all source code for a database project. Version control functions and build management facilities are also incorporated and help you manage and build projects. Once a project has been created, you can:

- Review a file’s history.
- Return to earlier versions of a file.
- Develop concurrently.

A project generally includes SQL script files that you can maintain and create in unison with your database administration and development cycle. Projects can also contain subfolders. You can create projects manually by inserting existing SQL script files. You can also create projects automatically by reverse-engineering a database schema or an existing version control project.

When administering or developing SQL database schemas, SQL source code files are the foundation of effective change management for database objects. The DDL commands used to create database objects on SQL database servers are often in a constant state of flux as new columns and constraints are added to table schemas or stored procedure logic is changed. The ability to track and store these changes to files alleviates any disruption in the development environment.

Lengthy script files containing the DDL to compile stored procedures and triggers on a database server such as Oracle or Sybase Adaptive Server go through constant revisions similar to C program files and word processing documents. The Project Management facilities let you effectively monitor revisions for your database servers.

Topics

- Create a New Project
- Working With Projects
Create a New Project

Step-by-step wizards guide you through the process of creating a new project. You have a variety of options to choose from when you create a new project. You can create new projects:

- From a database.
- From existing files.
- From a version control project.
- Without initialization.

The New Project dialog box lets you select how you want to create a new project. Using the New Project dialog box, you can name, specify a file location, and provide a description of the project.
New Project Dialog Box

The New Project dialog box lets you select how you want to create a new project. Using the New Project dialog box, you can name, specify a file location, and provide a description of the project.

The table below describes the options and functionality of the New Project dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Lets you enter a name for the project.</td>
</tr>
<tr>
<td>Location</td>
<td>Lets you type or browse and locate a directory for the project. NOTE: This is set as the working directory for your project.</td>
</tr>
<tr>
<td>Description</td>
<td>OPTIONAL: Lets you enter a description of the project.</td>
</tr>
<tr>
<td>Initialize New</td>
<td>Lets you select how you want to create a new project.</td>
</tr>
<tr>
<td>Project</td>
<td>From Database - Lets you reverse engineer an existing database. From Existing Files - Lets you create a project from scratch, or use an existing project. From Version Control Project - Lets you reverse-engineer a project from existing version control system projects. This is helpful for users who have already created database projects in their version control systems. Do Not Initialize - Lets you create an empty project where you can later add files and/or database objects.</td>
</tr>
</tbody>
</table>

Completing the New Project Dialog Box

To complete the New Project Dialog Box, do the following:

1. On the File menu, select New, and then Project.

The New Project Dialog Box opens.

2. In Name, enter a name for the project.

3. In Location, type or browse and locate a directory for the project.

4. OPTIONAL: In Description, lets you enter a description of the project.

5. In Initialize New Project, select how you want to create a new project.

6. Click OK.
Create a New Project From a Database

A context-sensitive wizard reverse-engineers all or part of an existing database. It lets you create a project containing files based on the relevant object types. A separate file is created for each database object.

Reverse engineering is a powerful tool for analyzing, controlling, and documenting existing database objects. You can use the extracted SQL source code for archival and reference purposes.

**Note:** The project script file build order is automatically discovered and set by referencing the system catalog to determine dependencies.

To start a new project from a database

1. Select **File > New > Project**. The **New Project** dialog box opens.

2. Complete the **New Project** dialog box, ensuring you select the **From Database** option, and then click **OK**. The **Reverse Engineer Wizard** opens.

3. Use the following table as a guide to understanding and setting options in the wizard:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Tasks and Settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection</td>
<td>Source Datasource</td>
<td>Lets you select the datasource for which you want to start a project.</td>
</tr>
<tr>
<td>Catalogs (only displayed for multiple database DBMS datasources)</td>
<td>Source Database</td>
<td>Lets you select one or more databases for which you want to start a project.</td>
</tr>
<tr>
<td>Object Selection</td>
<td>Schemas</td>
<td>Opens a dialog that lets you narrow the choice of candidate objects by selecting only those associated with specified schema/owners.</td>
</tr>
<tr>
<td>Object Types</td>
<td></td>
<td>Lets you select the object types that will be extracted. You can use the expand/collapse icons to hide and show the dependent object types for each object. As you select object types, all objects of that type (that satisfy the <strong>Schemas</strong> criteria) are made available for selection in the <strong>Objects</strong> list. Selected dependent object types are also made available in the <strong>Objects</strong> list. For information on setting the dependent object type automatically selected to be extracted along with each object type, see <strong>DDL Extract Options</strong>.</td>
</tr>
<tr>
<td>Objects</td>
<td></td>
<td>Lets you select the specific objects that will be extracted. For each object selected, you can also select the specific dependent objects that are to be extracted.</td>
</tr>
</tbody>
</table>
Create a New Project From a Database

**Options**

This panel lets you choose extraction options and view an Example Preview script that is updated as you choose options. It also lets you save your options choices as a template, with an option to use the saved template as the default. Click Finish when ready to proceed with the extraction.

**Execute**

Displays the status of the extraction with details on the number of objects retrieved, the number of errors detected, and the elapsed time. On completion, the schema definition is stored in the file you specified on the previous panel. Filter options (Show All, Show Errors, and Show Warnings) let you display specific types of messages generated during the extraction process. When the extraction completes, you can also use the following options:

- **Continue** Adds the individual files for each object to the project.
- **Report** Opens a detailed report on the results of the schema extraction.
Create a New Project From Existing Files

When creating a new project, you can start by adding files of the following types:

- Scripts (.sql)
- DDL (.ddl)
- Procedures (.prc, .pro)
- ER/Studio files (.dml)
- Queries (.qry)
- Text files (.txt)
- VB Script files (.vbs)
- JScript files (.js)
- Web files files (.html, .htm, .asp)

To create a new project from an existing file, do the following:

1. On the File menu, click New, and then click Project.

The New Project dialog box opens.

2. Complete the New Project dialog box and select the From Existing Files option.

3. Click OK.

The Add File(s) to Project dialog box opens.

4. Use the dialog to locate the directory containing the files, and select one or more files to add to the project.

5. When you finish, click Open.

Topics

- Add File(s) to a Project.
Create a New Project From a Version Control Project

You can reverse-engineer a project from existing version control system projects. This is helpful if you have already created database projects in a version control system.

**Note:** The Intersolv PVCS API does not support the creation of a project from a source code control project.

You can also create a project from a version control project that contains sub-directories, while including files from those sub-directories in your project.

To create a new project from a Version Control project, do the following:

1. On the **File** menu, click **New**, and then click **Project**.

The **New Project** dialog box opens.

2. Complete the **New Project dialog box** and select **From Version Control Project**.

3. Click **OK**.

The **Choose project from (Version Control name)** dialog box opens.

4. Select the project or files you want to include, and then click **OK**.

The **Files to be included in (project path)** dialog box opens.

5. Select the project of files you want to include, and then click **OK**.
Create a New Project Without Initialization

You can simply create a project with any further initialization. You can subsequently use the following topics to add additional resources:

- Add files.
- Add database objects.

To create a new project without initialization, do the following:

1. On the File menu, click New, and then click Project.

The New Project dialog box opens.

2. Complete the New Project dialog box and select the Do Not Initialize option.

3. Click OK.
Working with Projects

A project is similar to a file system. Both are a collection of files that you create and maintain. Because projects are hierarchical, you can place a subfolder under another project, and nest subfolders. Once you have created a new project, use the following topics to help you maintain and modify the project.

Topics

- New Project Dialog Box
- Opening an Existing Project
- Opening a Recent Project
- Closing a Project
- Build Project
- Set Build Order
- Add Database Object File(s) to Project Wizard
- Execute Project Files
- Add File(s) to a Project
- Open a File from a Project
- Subfolders
- Project Properties
- Confirm Delete Dialog Box
Opening an Existing Project

To open an existing project, do the following:

1. On the **File** menu click **Open Project**.

The **Open Project** dialog box opens.

2. In **File name**, type the name and location of the project or use browse to locate the project.

**Note:** Project files are designated with a *.epj extension.

3. Click **Open**.

The **Project Tab** containing the project opens.

**Topics**

- [Working with Projects](#)

Opening a Recent Project

To open a recent project, do the following:

1. On the **File** menu select **Recent Projects**, and then select a project.

The **Project Tab** containing the project opens.

**Topics**

- [Working with Projects](#)

Closing a Project

To close a project, do the following:

1. On the **File** menu, click **Close Project**.

2. On the **Project Tab**, right-click and then click **Close Project**.

**Topics**

- [Working with Projects](#)
**Build Project**

The Build Project dialog box lets you:

- Generate a project build script and display it in a SQL window.
- Execute the project build immediately on build target.
- Schedule a project build.

The table below describes the Build Project dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datasource</td>
<td>Displays the target datasource.</td>
</tr>
<tr>
<td>Database</td>
<td>Displays the target database.</td>
</tr>
<tr>
<td>Build subfolders</td>
<td>Select to include subfolders.</td>
</tr>
<tr>
<td>Generate a Project Build Script and Display it in a SQL window.</td>
<td>Select to generate the project build script and have it opened in a SQL window.</td>
</tr>
<tr>
<td>Execute Project Build Immediately on Build Target</td>
<td>Select to execute build immediately.</td>
</tr>
<tr>
<td>Schedule Project Build for a Later Time</td>
<td>Select to schedule the build and then specify optional options.</td>
</tr>
</tbody>
</table>

**Completing the Build Project Dialog Box**

To complete the Build Project dialog box, do the following:

1. On the **File** menu click **Open Project**.

2. In **File name**, type the name and location of the project or use browse to locate the project.

   **Note:** Project files are designated with a *.epj extension.

3. Click **Open**.

4. On the **Project Tab**, right-click the target project, and then select **Build**.

The **Build Project** dialog box opens.

5. Select options.

6. Click **OK**.
Set Build Order

You can specify the order in which you want your project files built in the Set Build Order dialog box. If you created your project manually or from a version control project, you must specify a build order, otherwise the files are built in the order that they appear in the tree of the Project Tab.

Setting Build Order

1. On the File menu click Open Project.

The Open Project dialog box opens.

2. In File name, type the name and location of the project or use browse to locate the project.

Note: Project files are designated with a *.epj extension.

3. Click Open.

The Project Tab containing the project opens.

4. On the Project menu, click Build Order.

The Set Build Order dialog box opens.

5. Click the files you want to move and then click the Up and Down to change the order to build the files.

6. When you finish specifying the order, select OK.

Note: The next time you build the project, the new build order is used.
Add Database Object File(s) to Project Wizard

You can add database objects to an existing project using a simple wizard that can reverse-engineer an entire database or any portion of it. This lets you keep your project in sync with databases where objects are constantly being created and updated.

Completing the Add Database Object File(s) to Project Wizard

To add database objects to a project, do the following:

1. On the File menu click Open Project.

The Open Project dialog box opens.

2. In File name, type the name and location of the project or use browse to locate the project.

Note: Project files are designated with a *.epj extension.

3. Click Open.

The Project Tab containing the project opens.

4. On the Project menu, click Add Database Objects.

The Reverse Engineer Wizard opens.

5. Use the information in Create a New Project From a Database to complete the wizard.
Execute Project Files

You can directly execute project script files from the Project Tab using the File Execution Facility. You can also execute multiple scripts in parallel against different datasources. If a file has been placed under version control, you need to perform a Check Out operation to execute the file. Otherwise, the file opens in read-only mode.

To execute project files, do the following:

1. On the Project Tab, right-click the files you want to execute, and then click File Execution Facility.

The Script/File Execution Facilities dialog box opens.

Add File(s) to a Project

You can add external files to your project. This lets you manipulate and expand your project as needed.

To add files to a project from, do the following:

1. On the Project menu, click Add Files.

The Add Files to Project dialog box opens.

2. Use the dialog to locate the directory containing the files you want to add to the project and then select the individual files to be added.

3. When ready, click Open.

Open a File from a Project

You can open a file directly from the Project Tab using a number of different methods.

To open a file from a project, do the following:

1. On the Project Tab, right-click the file(s) you want to open, and then click Open.

The file(s) open in a new SQL window.
Subfolders

Subfolders help categorize your source code files. On the Project Tab of the Database Navigator/Explorer, you can:

- Create subfolders.
- Delete subfolders.
- Rename subfolders.
- Sort subfolders.

Creating a New Subfolder

To create a new subfolder:

1. On the File menu click Open Project.

The Open Project dialog box opens.

2. In File name, type the name and location of the project or use browse to locate the project.

Note: Project files are designated with a *.epj extension.

3. Click Open.

The Project Tab containing the project opens.

4. On the Project menu, click New Subfolder.

5. Type the name of the new subfolder and then press Enter.

Deleting a Subfolder

To delete a project, do the following:

1. On the File menu click Open Project.

The Open Project dialog box opens.

2. In File name, type the name and location of the project or use browse to locate the project.

Note: Project files are designated with a *.epj extension.

3. Click Open.

The Project Tab containing the project opens.

4. On the Project Tab, right-click a subfolder, and then click Delete.
Subfolders

The Confirm Delete dialog box opens.

5. In the Confirm Delete dialog box, select the Delete local copy to delete the local copy of the subfolder, and then click OK.

Confirm Delete Dialog Box

The table below describes the options and functionality on the Confirm Delete Dialog Box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete local copy</td>
<td>Deletes the local copy of the subfolder.</td>
</tr>
</tbody>
</table>

For more information, see Deleting a Subfolder.

Renaming a Subfolder

To rename a subfolder, do the following:

1. On the File menu click Open Project.

The Open Project dialog box opens.

2. In File name, type the name and location of the project or use browse to locate the project.

Note: Project files are designated with a *.epj extension.

3. Click Open.

The Project Tab containing the project opens.

4. On the Project Tab, right-click a subfolder, and then click Rename.

5. Type the name of the new subfolder and then press Enter.

Sorting Subfolders

To sort a subfolder, do the following:

1. On the File menu click Open Project.

The Open Project dialog box.

2. In File name, type the name and location of the project or use browse to locate the project.

Note: Project files are designated with a *.epj extension.
3. Click **Open**.

The **Project Tab** containing the project.

4. On the **Project Tab**, right-click the subfolders you want to sort and then click **Sort**.

**Topics**

- [Working with Projects](#)

**Project Properties**

You can view properties of Projects, Subfolders, and individual files. The **Project Properties**, **Subfolder Properties**, and **File Properties** dialog boxes display information about the Projects, Subfolders, and files.

For more information, see [Working with Projects](#).

**Viewing Project Properties**

To view project properties, do the following:

1. On the **File** menu click **Open Project**.

The Open Project dialog box opens.

2. In **File name**, type the name and location of the project or use browse to locate the project.

**Note**: Project files are designated with a *.epj extension.

3. Click **Open**.

The **Project Tab** containing the project opens.

4. On the **Project Tab**, right-click one or more selected projects and then click **Properties**.

The **Project File Properties** or **Multiple Selection Properties** dialog box opens.

5. Complete the **Project File Properties dialog box** or **Multiple Selection Properties Dialog Box**.

6. Click **OK**.

**Multiple Selection Properties Dialog Box**

The table below describes the options and functionality of the Project Properties dialog box:
Project Properties

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Lets you type or edit the common description for the selected files.</td>
</tr>
<tr>
<td>Include In Build</td>
<td>Sets the files to be included in the build.</td>
</tr>
<tr>
<td>Object Type</td>
<td>Lets you associate a database object type with the file, as appropriate.</td>
</tr>
</tbody>
</table>

Project File Properties Dialog Box

The table below describes the options and functionality of the Project Properties dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Displays the name of the project.</td>
</tr>
<tr>
<td>Full Specification</td>
<td>Displays the project location.</td>
</tr>
<tr>
<td>Description</td>
<td>Displays the project description. OPTIONAL: Lets you type or edit the project description.</td>
</tr>
<tr>
<td>Associated Datasource</td>
<td>Lets you select a datasource for the project.</td>
</tr>
<tr>
<td>Associated Database</td>
<td>Lets you type the name of the database.</td>
</tr>
</tbody>
</table>

For more information, see Viewing Project Properties.

Viewing Subfolder Properties

To view subfolder properties, do the following:

1. On the File menu click Open Project.

The Open Project dialog box opens.

2. In File name, type the name and location of the project or use browse to locate the project.

Note: Project files are designated with a *.epj extension.

3. Click Open.

The Project Tab containing the project opens.

4. On the Project Tab, select a subfolder.

5. Right-click the subfolder, and then click Properties.

The Subfolder Properties dialog box opens.
6. Complete the Subfolder Properties dialog box.
7. Click OK.

Subfolder Properties Dialog Box

The table below describes the options and functionality of the Subfolder Properties dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Displays the name of the subfolder. You can enter or edit the subfolder name.</td>
</tr>
<tr>
<td>Full Specification</td>
<td>Displays the subfolder location.</td>
</tr>
<tr>
<td>Status</td>
<td>Displays the subfolder status.</td>
</tr>
</tbody>
</table>

For more information, see Viewing Subfolder Properties.

Viewing File Properties

To view file properties, do the following:

1. Click File and then Open Project.

The Open Project dialog box opens.

2. Type the project name or select the project.
3. Click Open.

The project opens on the Projects Tab.

4. On the Project Tab, select a file.
5. Right-click the file, and then click Properties.

The File Properties dialog box opens.

6. Complete the File Properties dialog box.
7. Click OK.

File Properties Dialog Box

The table below describes the options and functionality of the File Properties dialog box:
## Project Properties

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Displays the file name.</td>
</tr>
<tr>
<td>Full Specification</td>
<td>Displays the file location.</td>
</tr>
<tr>
<td>Description</td>
<td>Displays the file description. OPTIONAL: Type or edit the file description.</td>
</tr>
<tr>
<td>Include In Build</td>
<td>Sets the file to be included in the build.</td>
</tr>
<tr>
<td>Last Modified</td>
<td>Displays the date and time of the last modification.</td>
</tr>
<tr>
<td>Size</td>
<td>Displays the file size.</td>
</tr>
<tr>
<td>Status</td>
<td>Displays the file status.</td>
</tr>
<tr>
<td>Object Type</td>
<td>Displays the file object type. Select an object type if the file is unspecified.</td>
</tr>
</tbody>
</table>
Version Control

Version control archives files and tracks changes to files over time. With an integrated version control, you can easily track changes to database objects.

Version control addresses the following issues:

- Team Development By controlling access to a file so that only one person at a time can modify, it prevents accidental replacement or loss of another user’s changes.
- Version Tracking By archiving and tracking versions of source code files, you can retrieve them if necessary, thereby effectively creating files so that source code can be reused.
- Safety By adding database object scripts and files, it creates backups in case of loss, thereby ensuring a recovered version of source code.

When you create a project, you can immediately place the project into version control or you can Create a New Project From a Version Control Project. You can also add projects and files to version control later selecting Project menu, Version Control and Add To Version Control....

Version Control Integration

To use integrated version control features, you must have the version control client software installed on the same computer, or the MSSCCI plug-in for the selected Version Control System. You must select the appropriate version control on the Version Control Tab of the Option Editor.

DBArtisan supports all Version Control Systems compatible with MSSCCI. Other Version Control Systems not compatible with MSSCCI may work under certain conditions.

Note: 64 bit versions of DBArtisan can now use 32 bit MSSCCI providers by choosing to do so in the version control option page. Most providers are 32 bits only, so this allows users to continue to use the 64 bit version of our application even if the have a source control that has no 64 bit provider available.

Version Control Configuration

Information about how to configure a Version Control system is described in Version Control Options.

Using Version Control

Once you add a file or project to the version control, most functions found in the underlying version control system are available directly. Basic version control procedures include:
Version Control

- Get Latest Version
- Check Out
- Check In
- Undo Check Out
- Open
- Delete
- Remove from Version Control
- Sort
- Show History
- Show Difference
- Version Control Properties

**Note:** Version control functionality depends on your underlying version control system. For more information on version control procedures, consult the documentation included with your version control system.

**Version Control Icons**

The table below describes the icons related to Version Control files:
## Version Control

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Image]</td>
<td>File is not checked out by anyone.</td>
</tr>
<tr>
<td>![Image]</td>
<td>File is checked out non-exclusively and only by the user logged into source control.</td>
</tr>
<tr>
<td>![Image]</td>
<td>File is checked out non-exclusively only by a one user who is not the user logged into source control.</td>
</tr>
<tr>
<td>![Image]</td>
<td>File is checked out exclusively and only by the user logged in to source control.</td>
</tr>
<tr>
<td>![Image]</td>
<td>File is checked out exclusively and only by a user who is not the user logged in to source control.</td>
</tr>
<tr>
<td>![Image]</td>
<td>File is checked out by multiple users, including the user logged in to source control.</td>
</tr>
<tr>
<td>![Image]</td>
<td>File is checked out by multiple users, not including the user logged in to source control.</td>
</tr>
<tr>
<td>![Image]</td>
<td>Project file is not checked out by anyone.</td>

<tr>
<td>![Image]</td>
<td>Project file is checked out by multiple users, not including the user logged in to source control.</td>
</tr>
</tbody>
</table>

### Topics
- [Working with Projects in Version Control](#)
Version Control Functionality - Open

The Open functionality opens the selected file(s) with the application registered for the type(s) of the selected file(s).

Version Control Functionality - Delete

The Delete functionality deletes the local copy of the selected item from the tree. To remove a file from version control, see Remove From Version Control.

Version Control Functionality - Sort

The Sort functionality sorts the tree items alphabetically.

Version Control Functionality - Get Latest Version

The Get Latest Version functionality lets you access the latest version of a file for viewing only. The Get functionality creates a local copy of the most current version of a project file in your working folder. The file is read-only, so any modifications cannot be saved.

Before working with a project, you should perform a Get on the entire project to ensure that you are working with the latest copy of the project. You should also perform a project-level, recursive Get at intervals to ensure that you have the latest version of files, in the event that they have been altered by others working on the same project.

The following table describes the option and functionality on the Get from Version Control dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Files to Get</td>
<td>Lets you select file(s) to get latest version of.</td>
</tr>
<tr>
<td>Advanced</td>
<td>Click to open the Advanced Get Options dialog box.</td>
</tr>
</tbody>
</table>

Tip: You can specify the file directory in the Version Control option of the Options Editor. For details, see Version Control Options.

Getting Latest Version of a Project

To get the latest version of a project, do the following:

1. Click File and then Open Project....

The Open Project dialog box opens.

2. Type the project name or select the project.
3. Click **Open**.
The project on the **Projects Tab** opens.

4. Click the project or target files.

5. On the **Project** menu, click **Version Control**.
The **Version Control** menu opens.

6. Click **Get Latest Version**....
The **Get From Version Control** dialog box opens.

7. In the **Files to Get** box, click the project or files.

8. For advanced options, click **Advanced**.

9. Click **OK**.
The most current version of the file is written to your working directory.

### Getting Latest Version of a File

To get the latest version of a file, do the following:

1. On the **Project Tab**, right-click the target file(s) and select **Get Latest Version**....
The **Get From Version Control** dialog box opens.

2. In the **Files to Get** box, select the file(s).

3. For advanced options, click **Advanced**.

4. Click **OK**.
The most current version of the file is added to the **Project Tab**.

### Topics

- [Using Version Control](#)
Version Control Functionality - Check Out

The Check Out functionality retrieves a copy of one or more selected files and creates a writable working file copy in the working directory. You must perform a Check Out to edit any file that has been placed under version control.

You can check out a single file, multiple files at once or an entire project. A red check mark over the file icon indicates that the file has been checked out and is writable. This does not prevent other users from performing a Get or a Check Out on the file.

The following table describes the options and functionality on the Check Out File(s) dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Files to be Checked Out</td>
<td>Displays list of files that are eligible for check out. A black mark indicates that another user has the file(s) checked out.</td>
</tr>
<tr>
<td>Advanced</td>
<td>Click to open the Advanced Check Out Options dialog box.</td>
</tr>
</tbody>
</table>

**Tip:** You can specify the file directory in the Version Control Working Directory option of the Options Editor. For details, see Version Control Options.

Checking Out a Project

To check-out a project, do the following:

1. Click **File** and then **Open Project**.

The **Open Project** dialog box opens.

2. Type the project name or select the project.

3. Click Open.

The project opens on the **Projects** Tab.

4. Select the target project.

5. On the **Project** menu, click **Version Control**.

6. Select **Check Out**.

The **Check Out** dialog box opens.

7. In the **Files to Be Checked Out** box select the project.

8. For advanced options, click **Advanced**.

9. Click **OK**.
The project or files are checked out from version control and writes the most current version of the file to your working directory.

**Check Out a File**

To check out a file, do the following:

1. On the **Project** Tab, right-click the target file(s) and select **Check Out**.

   The **Check Out File(s)** dialog box opens.

2. In the **Check Out File(s)** dialog box select the files.

3. For advanced options, click **Advanced**.

4. Click **OK**.

The file(s) is checked out from version control and the most current version of the file is added to the **Project** Tab.

**Topics**

- [Using Version Control](#)
Version Control Functionality - Check In

After editing your files, you must Check In the revised file in order to save the changes you made to the file in a project. The Check In functionality stores the new version of the updated file in the current project. The Check In functionality is only available if you have Checked Out a file. You have the option to Check In an entire project or individual files.

**Tip:** You can specify the file directory in the Version Control Working Directory option of the Options Editor. For details, see [Version Control Options](#).

The table below describes the options and functionality on the Check In dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Files to be checked in</td>
<td>Lets you specify the file(s) to check in.</td>
</tr>
<tr>
<td>Keep checked out</td>
<td>Adds latest version(s) of file(s) to source control but keeps the file(s) checked out.</td>
</tr>
<tr>
<td>Comment</td>
<td>OPTIONAL: Lets you type an optional comment.</td>
</tr>
</tbody>
</table>

**Checking In a Project**

To check-in a project, do the following:

1. Click **File** and then **Open Project**.
2. The **Open Project** dialog box opens.
3. Type the project name or select the project.
4. Click **Open**.

The project opens on the **Project** Tab.

5. On the **Project** menu, click **Version Control**, and then **Check In**.

The **Check In** dialog box opens.

6. In the **Files to Be Checked In** box click the project or files.
7. To update the version control copy but keep the project or files checked out so that you can continue working, select the **Keep Checked Out** check box.
8. **OPTIONAL:** In the **Comment** text box type a description of the changes.
9. Click **OK**.

**Check In a File**

To check in a file, do the following:

1. On the **Project** Tab, right-click the target file(s) and select **Check In**.
The **Check In File(s)** dialog box opens.

2. In the **Check In File(s)** dialog box select the files.

3. To update the version control copy but keep the files checked out so that you can continue working, select the **Keep Checked Out** check box.

4. **OPTIONAL:** In the **Comment** text box type a description of the changes.

5. Click **OK**.

**Topics**

- **Using Version Control**
Version Control Functionality - Undo Check Out

If you decide that you do not want to save any revisions you have made to a checked out file, you can undo the procedure that releases the lock placed on the project or file. However, you do not have the option of deleting the local copy of the file.

**Tip:** You can specify the file directory in the Version Control Working Directory option of the Options Editor. For details, see [Version Control Options](#).

The table below describes the options and functionality on the Undo Check Out dialog box.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cancel the checkout for the following files</td>
<td>Lets you specify the files to undo checkout.</td>
</tr>
<tr>
<td>Advanced</td>
<td>Opens the Undo Check Out Advanced Options dialog box that lets you leave, replace, or apply the default action to your local copy.</td>
</tr>
</tbody>
</table>

**Undoing Checkout for a Project**

To undo a checkout, do the following:

1. Click **File** and then **Open Project**.
   
   The **Open Project** dialog box opens.
   
   2. Type the project name or select the project.
   
   3. Click **Open**.
      
      The project opens on the **Project** Tab.
      
      4. Click the project.
      
      5. On the **Project** menu, click **Version Control**.
      
      6. Click **Undo Check Out**.
      
      The **Undo Check Out** dialog box opens.
      
      7. In the **Cancel the check out for the following files** box of the **Undo Check Out** dialog box, click the project.
      
      8. Click **OK**.
         
         **Note:** If you Undo Check Out, you lose any changes you have made to the local copy of your project.
Undoing Checkout for a File

To undo checkout for a file, do the following:

1. On the **Project** Tab, right-click the target file(s) and select **Undo Checkout**.

The **Undo Checkout** dialog box opens.

2. In the **Cancel the check out for the following files** box of the **Undo Check Out** dialog box, click the project.

3. Click **OK**.

   **Note:** If you Undo Check Out, you lose any changes you have made to the local copy of your file(s).

**Topics**

- [Using Version Control](#)
Version Control Functionality - Show History

The Show History functionality lets you view the history of version control files.

Showing History for a Project

To show history, do the following:

1. Click File and then Open Project.

The Open Project dialog box opens.

2. Type the project name or select the project.

3. Click Open.

The project opens on the Project Tab.

4. Click the target file.

5. On the Project menu, click Version Control, and then select Show History.

The History dialog box opens.

Note: The History dialog box depends on your version control system.

Showing History for a File

To show history, do the following:

1. On the Project Tab, right-click the target file(s) and select Show History.

The History dialog box opens.

Note: The History dialog box depends on your version control system.

Topics

- Using Version Control.
Version Control Functionality - Show Differences

The Show Differences functionality lets you view any differences between the current files in your working folder and the master files in the version control database. You cannot make changes to the files from this dialog box because it is used for display purposes only.

Viewing Project Differences

To view project differences, do the following:

1. Click File and then Open Project.

The Open Project dialog box opens.

2. Type the project name or select the project.

3. Click Open.

The project opens on the Project Tab.

4. Click the target file.

5. On the Project menu, click Version Control.

6. Click Show Differences.

The Differences dialog box opens.

If the file in your working directory is the same as the one in the project, a message tells you they are identical. If there are differences, the Differences dialog box from your version control system opens and displays the two versions of the file side-by-side, highlighting any differences.

7. In the Differences dialog box, you can maneuver through the files by using the Up and Down arrows.

8. To set Diff Options, click the Options button.

Note: The Differences dialog box and Options depend on your version control system.

Showing History for a File

To show history, do the following:

1. On the Project Tab, right-click the target file(s) and select Show History.

The Difference dialog box opens.
2. In the **Difference** dialog box, you can maneuver through the files by using the **Up** and **Down** arrows.

**Note:** The **Difference** dialog box and options depend on your version control system.

**Topics**

- **Using Version Control.**
Version Control Functionality - Remove from Version Control

The Remove from Version Control functionality lets you remove entire projects or files from version control.

**Note:** This functionality does not destroy the file permanently from the source control system or remove the local copies of the file(s).

**Removing a Project from Version Control**

To remove a project from Version Control, do the following:

1. Click **File and then** Open Project.

The **Open Project** dialog box opens.

2. Type the project name or select the project.

3. Click **Open**.

The project opens on the **Project** Tab.

4. On the **Project** menu, click **Version Control**, and then click **Remove from Version Control**.

The **Remove File(s)** dialog box opens.

5. To permanently destroy the project select the check box, click **OK**.

**Removing a File from Version Control**

To remove a file from Version Control, do the following:

1. On the **Project**, right-click the target file(s) and select **Remove from Version Control**.

The **Remove File(s)** dialog box opens.

2. Select the file(s) in the **Files to be Removed from Version Control** box.

3. Click **OK**.
Version Control Properties

The Version Control File Properties dialog box displays general information and check out status, links, and paths.

Viewing Version Control Properties for a Project

To view the version control properties, do the following:

1. Click File and then Open Project.
The Open Project dialog box opens.
2. Type the project name or select the project.
3. Click Open.
The project opens on the Project Tab.
4. Click the target file.
5. On the Project menu, click Version Control, and then Version Control Properties.
The Version Control Properties dialog box opens.
6. Review properties.
7. Click Close.

Viewing Version Control Properties for a File

To view the version control properties, do the following:

1. On the Project Tab, right-click the target file(s) and select Version Control Properties.
The Version Control Properties dialog box opens.
2. Review properties.
3. Click Close.

Topics

- Using Version Control.
Working with Projects in Version Control

Projects can exist independently of version control. You can add an entire project to version control at any point. When you decide to place a project under version control, a project is created on the underlying version control system that has been specified.

Once a project or file has been added to version control, the features of your version control system are available directly from the Project Tab. Any changes you make to a project or file from within DBArtisan are simultaneously changed in your version control system.

The table below describes the options and functionality on the Add to Version Control dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Files to be added</td>
<td>Lets you select files to add to Version Control.</td>
</tr>
<tr>
<td>Comment</td>
<td>OPTIONAL: Lets you add a comment.</td>
</tr>
<tr>
<td>Check out immediately</td>
<td>Select to add file and keep it checked-out.</td>
</tr>
<tr>
<td>Store only latest</td>
<td>Select to add the latest version.</td>
</tr>
<tr>
<td>Remove local copy</td>
<td>Select to add file and remove the local copy.</td>
</tr>
</tbody>
</table>

Completing the Add to Version Control Dialog Box

To add a project to version, do the following:

1. Click File and then Open Project.

The Open Project dialog box opens.

2. Type the project name or select the project.

3. Click Open.

The project opens on the Project Tab.

4. On the Project menu, click Version Control.

The Add to Version Control dialog box opens.

5. Click Add to Version Control.

6. Select options needed.

7. Click OK to add a project, and then click Create.
Note: The project file icon dims to indicate that the project has been placed under version control.

Topics

- Working with Projects.
# Tools

The **Tools** menu offers the following:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Find in Files</strong></td>
<td>Lets you find a phrase or character in your files.</td>
</tr>
<tr>
<td><strong>Database Search</strong></td>
<td>Lets you search for objects whose DDL contains specified strings.</td>
</tr>
<tr>
<td><strong>Script/File Execution Facilities</strong></td>
<td>Two stand-alone utilities that let you type or paste SQL statements to be executed or execute a script in a file.</td>
</tr>
<tr>
<td><strong>Scheduling</strong></td>
<td>Describes tools you can use to schedule tasks.</td>
</tr>
<tr>
<td><strong>Visual Difference</strong></td>
<td>Lets you compare two files or database objects.</td>
</tr>
<tr>
<td><strong>Query Builder</strong></td>
<td>Lets you build queries using a visual interface.</td>
</tr>
<tr>
<td><strong>Import Data</strong></td>
<td>Lets you import data from <code>.xls</code>, <code>.sql</code>, <code>.tab</code>, or <code>.csv</code> files.</td>
</tr>
<tr>
<td><strong>SQL Profiler</strong></td>
<td>Provides access to the PL/SQL Profiler.</td>
</tr>
<tr>
<td><strong>Table/Index Size Estimator</strong></td>
<td>Provides access to the <strong>Estimate Size</strong> object action.</td>
</tr>
<tr>
<td><strong>Embarcadero Product Menu Commands</strong></td>
<td>Correspond to installed or available Embarcadero Technologies products.</td>
</tr>
<tr>
<td><strong>Available DBMS Utility Menu Commands</strong></td>
<td>Lets you start third party utilities.</td>
</tr>
<tr>
<td><strong>Code Workbench</strong></td>
<td>Lets you set up keystroke-saving shortcuts that can be used in the SQL Editor.</td>
</tr>
<tr>
<td><strong>Customize (Tools menu)</strong></td>
<td>Lets you customize the user interface and set up shortcuts.</td>
</tr>
<tr>
<td><strong>Options (Tools menu)</strong></td>
<td>Lets you configure features and specify preferences.</td>
</tr>
<tr>
<td><strong>Data Editor</strong></td>
<td>Provides a live data editor.</td>
</tr>
</tbody>
</table>
Find in Files

The Find in Files tool lets you search files for a phrase or character.

To search files for specified characters:

1. On the Tools menu, select Find in Files. A Find in Files dialog opens.
2. Use the table below as a guide to choosing settings on this dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Find what</td>
<td>Specifies the character(s) or phrase you want to find. Use the browse arrow button next to the textbox to choose options from a pop-up list.</td>
</tr>
<tr>
<td>In files/file types</td>
<td>Specifies the files in which to search for the character(s) or phrase. Either enter the filename(s) in the drop-down box, or click the arrow to choose a file type.</td>
</tr>
<tr>
<td>In folder</td>
<td>Specifies the directory where the file(s) is located. Click the browse button to view your Windows Explorer.</td>
</tr>
</tbody>
</table>

Other common Search options

The Find in Files dialog lets you specify the following common search options: Match whole word only, Match case, Regular Expression (tells the application whether the specified character(s) is a regular expression), Look in subfolders, and Output to Pane 2 (displays the results in another window).

3. When ready, click Find.
Database Search

The powerful Database Search tool lets you search for objects whose DDL contains a specified character string, across multiple databases.

Platform Availability

- DB2 LUW
- DB2 z/OS
- ITB/FBD
- MySQL
- ORCL
- PSTGRS
- SQL SVR
- SYB ASE
- SYB IQ

To find instances of a string on multiple databases:

2. Use the following table as a guide to understanding and modifying the settings on the panels of this wizard:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Settings and tasks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the datasources you want to search</td>
<td>Depending on the DBMS platform, you may also be able to further qualify by database, user, or schema.</td>
</tr>
<tr>
<td>Select the objects you want to search</td>
<td>Lets you specify the character string to search for, select a case matching setting, and specify the object types that are to be searched. Depending on the DBMS platform, searchable object types are defaults, foreign keys, functions, indexes, materialized tables, package bodies, packages, primary keys, procedures, rules, tables, triggers, unique keys, and views.</td>
</tr>
</tbody>
</table>

1. Click Finish to start the search.

A progress dialog box is displayed while the search runs. When the search completes, the results open in a Database Search window. The left pane lists all objects whose DDL satisfied the search. The right pane displays the DDL of a selected object. Lines containing the specified character string are flagged.
When viewing results, the following options are available from the Database Search window toolbar:

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search</td>
<td>Reopens the Database Search wizard with the most recent settings specified. This lets you further qualify settings for a new search.</td>
</tr>
<tr>
<td>Criteria</td>
<td>Opens a window displaying the case matching option and character string specified for the search.</td>
</tr>
<tr>
<td>Open</td>
<td>Opens the selected object in an object editor. For information on using object editors, see Modifying objects using editors.</td>
</tr>
<tr>
<td>Extract</td>
<td>Extracts the DDL for a selected object to a SQL editor window. For more information, see Using the SQL Editor.</td>
</tr>
<tr>
<td>Print</td>
<td>Lets you print the target object SQL.</td>
</tr>
</tbody>
</table>
Script/File Execution Facilities

Two stand-alone utilities establish multiple threads and database connections, letting you simultaneously execute SQL statements against multiple cross-DBMS platform datasources.

- Script Execution Facility lets you type or paste SQL statements to be executed
- File Execution Facility lets you load files containing SQL statements to be executed

Both utilities also work in conjunction with supported scheduling facilities, letting you schedule execution jobs. After completing a scheduled job, a results report lists errors, verifies script execution, and details the output of the job. Results can be automatically sent to any e-mail or network recipients.

Both utilities use a tabbed dialog box where you set the parameters and options for the script execution.

To execute SQL using one of these facilities

1. On the Tools menu, select either Script Execution Facility or File Execution Facility.

A tabbed dialog opens. It lets you provide the SQL to be executed and provide additional details.

2. Use the following table as a guide to selecting settings on the tab of this dialog:

<table>
<thead>
<tr>
<th>Tab</th>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Script (Script Execution Facility only)</td>
<td>Script box</td>
<td>Lets you type or paste a script.</td>
</tr>
<tr>
<td>Files (File Execution Facility only)</td>
<td>Show Full File Paths</td>
<td>Select to display the full path. Deselect to display only the file name.</td>
</tr>
<tr>
<td></td>
<td>File Name</td>
<td>Displays the file names.</td>
</tr>
<tr>
<td></td>
<td>Add and Remove</td>
<td>Use these controls to add or remove files.</td>
</tr>
<tr>
<td></td>
<td>View</td>
<td>Opens the View File dialog box.</td>
</tr>
<tr>
<td></td>
<td>Up and Down</td>
<td>Use these controls to move the selected file up or down in the list.</td>
</tr>
</tbody>
</table>
### Script/File Execution Facilities

<table>
<thead>
<tr>
<th>Target</th>
<th>Select the Target Datasource(s) to Execute the Script Against</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Only Connected Datasources - Displays only datasources that are currently connected in the Datasource grid. All DBMS Types - Displays all DBMS types in the Datasource grid.</td>
</tr>
</tbody>
</table>

**Datasource grid**

Displays the target datasource(s) to execute the script/file against. Select a datasource name. If the datasource has multiple databases, type in a database in the Database box.

<table>
<thead>
<tr>
<th>Output</th>
<th>Graphical Output</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If selected, specifies a graphical output.</td>
</tr>
</tbody>
</table>

**File Output**

If selected, specifies a file output. Directory - Type or browse to enter the full path and directory name in which you want to place the output file. File Type - Specifies a file type. Include column titles when saving - If selected, lets you save column titles. Open files with registered applications - If selected, opens files with registered applications.

<table>
<thead>
<tr>
<th>Notify</th>
<th>Job Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Lets you enter a job description. This description will be the subject of the notification E-mail.</td>
</tr>
</tbody>
</table>

**E-mail address**

Lets you enter E-mail addresses. Separate each E-mail address with a semicolon (;).

**Net Send User Names**

Lets you enter net send user names. Separate each name with a semicolon (;).

3. When ready, click **Execute**.
Scheduling

You can schedule routine tasks and jobs using the following utilities:

- Microsoft Task Scheduler
- ETSQLX Command Line Utility

Microsoft Task Scheduler

You can use the Microsoft Task Scheduler to schedule jobs. The Microsoft Task Scheduler is included with various Microsoft applications. If you do not have this program on your system, the first time you attempt to schedule a job, you are offered a link to the Microsoft Web site where you can download the Microsoft Task Scheduler at no cost.

*Note:* The ETSQLX command line utility runs a scheduled job even if the application is not running. For more information, see ETSQLX Command Line Utility.

To open the Microsoft Job Scheduler

1. On the **Tools** menu, click **Scheduler**.
2. Use the associated online Help for assistance with using this Microsoft utility.

ETSQLX Command Line Utility

The ETSQLX command line utility, is a multi threaded, cross-platform, SQL scripting engine. You can use ETSQLX in conjunction with the Microsoft Task Scheduler to schedule and automate routine jobs. ETSQLX creates batch files (with the extension.cfg) containing commands to execute automated and scheduled jobs. ETSQLX creates a directory, CFG, in which it stores the.cfg files. You can run.cfg files directly from the command line.

*Note:* ETSQLX supports.csv, .tab, .htm, and.html formats for result reports attachments.
Visual Difference

You can compare two text files or database objects (extracted DDL). Using the **Visual Diff** dialog box, you can easily synchronize and analyze database objects or files across multiple database platforms. The files are displayed side by side. The Visual Difference utility highlights any differences between two files. Viewing differences between objects and files helps you negotiate between the different phases of development as well as providing a visual aid to rapidly changing and evolving production environments.

**Note:** Because contents of the **Visual Diff** dialog box are read-only, you cannot modify files or objects directly from this dialog box.

**To open the Visual Diff dialog box**

1. On the **Tools** menu, click **Visual Diff**.

The **Visual Diff** dialog box opens.

![Visual Diff dialog box](image)

The **Visual Diff** dialog box is composed of two panes; the left pane displays your source object or file and the right pane shows your target object or file. The toolbar provides the basic visual search functions.

**Topics**

- **Setting Visual Difference options**
- **Specifying the Files or Database Objects to Compare**
Setting Visual Difference options

The **Visual Diff** dialog box lets you set display and comparison options to help you customize the dialog box to view differences in a comprehensive manner.

To set options for visual difference operations

1. On the **Tools** menu, click **Visual Diff**.
2. Click the **Options** icon on the toolbar.

The **Visual Diff Options** dialog box opens.

3. Use the following table as a guide to setting options in this dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display Line Numbers</td>
<td>Indicates that line numbers should be displayed.</td>
<td>Off</td>
</tr>
<tr>
<td>Display Hidden Characters</td>
<td>Indicates that hidden, nonprintable characters should be displayed.</td>
<td>Off</td>
</tr>
<tr>
<td>Ignore White Space</td>
<td>Indicates that White Space (such as spaces, carriage returns, line feeds, and tabs) should be ignored. If this option is set on, text will be considered equivalent regardless of white space. Otherwise the text will be shown as being different.</td>
<td>On</td>
</tr>
<tr>
<td>Ignore Hidden Characters</td>
<td>Indicates that nonprintable characters should be excluded.</td>
<td>Off</td>
</tr>
<tr>
<td>Ignore Case</td>
<td>Indicates that case should not be a differentiating factor.</td>
<td>On</td>
</tr>
</tbody>
</table>

4. Click **OK**.
Specifying the Files or Database Objects to Compare

You can compare two files or database objects side-by-side in the Visual Diff dialog box. The file or object you want to compare is called the source. The file or object you want to compare the source to is the target.

To open the source and target

2. On the toolbar, click the down arrow next to the Source icon and then click File or Database Object.

The Select the 1st File to Compare or Select the 1st Database Object to Compare dialog box opens.

3. Take one of the following actions:
   - Use the Select the 1st File to Compare dialog box to locate and select the source file
   - Use the Select the 1st Database Object to Compare dialog box to navigate the datasource tree to locate and select the source database object.

4. Repeat those actions to select a target file or database object. A progress dialog is briefly displayed, showing processing of the differences between the source and target.

Note: The Visual Difference Utility highlights all differences between the two files.

Once you have added the source and target, you can navigate back and forward among the highlighted differences, search the source or target for character strings, or print the contents of the source or target pane.

Topics

- Navigating to the next or previous highlighted difference
- Finding character strings in the source or target
- Printing a Pane of the Visual Difference Dialog Box
- Visual Difference
Navigating to the next or previous highlighted difference

You can navigate through the Visual Diff dialog box using the up and down arrow buttons. You can move back and forth between highlighted differences in your compared files or database objects.

To select the next or previous difference in the source and targets

1. Open the Visual Diff dialog box and load the source and target files or database objects. For details, see Specifying the Files or Database Objects to Compare.

2. On the toolbar, click the down arrow to go to the next difference or the up arrow to go to the previous difference.

Topics

- Visual Difference.
Finding character strings in the source or target

The Visual Diff dialog box lets you search for text in your files or database objects.

To search for text in the source or target pane

1. Open the Visual Diff dialog box and load the source and target files or database objects. For details, see Specifying the Files or Database Objects to Compare.
2. Place your cursor inside the pane you want to search.
3. Click the Find icon on the Visual Difference toolbar.

The Find dialog box opens.

4. In the Find What box, enter the search string.
5. Use the Match... controls specify whole word searching or case sensitivity.
6. Click Find Next to find the next occurrence of the search string.

After specifying the search string in a visual difference session, you can repeat the search without opening the Find dialog.

To find the next instance of the search string

1. Click the Find Next icon on the Visual Difference toolbar.

Topics

- Visual Difference.
Printing a Pane of the Visual Difference Dialog Box

You can print each pane of the Visual Diff dialog box.

To print the target or source pane

1. Open the Visual Diff dialog box and load the source and target files or database objects. For details, see Specifying the Files or Database Objects to Compare.
2. Position your cursor inside the pane you want to print.
3. Click the Print icon on the Visual Difference toolbar.
4. Click OK.

Note: You can only print one pane of the Visual Diff dialog box at a time.

Topics

- Visual Difference.
SQL Profiler

The Tools menu provides access to the SQL Profiler, a license-specific module:

- For licensing information, see Licensing Your Product
- For detailed information on using the profiler, see PL/SQL Profiler.

Table/Index Size Estimator

The Tools menu provides access to the Estimate Size object action, available against Oracle and Sybase ASE tables and indexes. For details, see Estimate Size.

Import Data

It is often necessary to import data into database tables from external sources. You may need to bring sample data into a database to establish test case scenarios or import data for use in the real world. Business analysts, for example, often use spreadsheets from outside sources. Putting such data into tables can help them perform detailed queries and make informed decisions based on meaningful data.

The Import Data tool lets you import data from a Microsoft Excel (.xls) file or any SQL data file format in which data values are stored in plain-text form and delimited by tab, semicolon, comma, space, or other user-specified character (such as .sql, .tab, or .csv).

Note: When you import a text file, the wizard may give the impression of stalling. Press ESC and you should be able to continue without further incident.

To Open the Import Data Wizard:

1. Connect to the datasource to which you want to import data and ensure that the datasource is selected. For more information, see Connecting to Datasources.

2. On the Tools menu, select Import Data. The Import Data Wizard opens.

3. Use the following table as a guide to providing information as you work through the panels of this wizard:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Properties</td>
<td>Specify the file to be used in this data load operation</td>
<td>Type the path and name of the file that you want to import from or use the browse button to locate and select the file.</td>
</tr>
<tr>
<td></td>
<td>Which table do you want to load data into?</td>
<td>If working against a Sybase or SQL Server datasource, select the Catalog of tables. Select the Schema that owns the target table. Select the particular Table where you want to import the data.</td>
</tr>
</tbody>
</table>
Import Data

Delimiter: What character delimited the columns in the data file?
Choose among Tab, Semicolon, Comma, or Space. Alternatively, select Other and type the specific delimiting character.

First Row Contains Field Names: By choosing this, if the first row contains column names, these will be displayed as the first row of the file. You can still change column mappings if you want. If you do not select this, generic Field 1, Field 2,... Field n will indicate column mappings.

Column Mapping:
Note: You must map all mandatory (NOT NULL) column fields to a column heading before you can enable the Finish button and import the data. To map columns, click the grey bar at the top of the grid and a drop-down list appears. The names in this drop-down list are columns in the table that’s going to receive the data. These need to sync up to the data that’s being imported. Red, or mandatory columns, turn blue in the column list when they have been assigned. A maximum of 10 rows are displayed here to make mapping columns easier. All rows will be imported when the job completes. If there are more columns in the file you are importing than in the receiving table, the extra columns will be ignored and you can create the insert statements. You cannot complete the import operation if columns are mapped more than once. The import operation will not let you generate invalid columns.

Excel Column Mapping (.xls files only):
Sheet: If the file you selected has more than one sheet, identify the worksheet that has the data you want to import.

Start/End Cell: Identify the starting and ending cells of data you want to import and click Refresh. Or, accept the default cells.

4. Click Finish.
Query Builder

Query Builder is a database productivity tool that lets you construct, structure, and manipulate up to five different types of queries simultaneously. It includes a separate graphical interface that opens within your current workspace. You can run Query Builder against all Embarcadero Technologies supported database platforms.

Query Builder displays the interconnections of your queries as you work. The powerful visual components of Query Builder let you see your query grow and change to fit your needs. Query Builder eases the task of drawing data from tables by automatically creating correct SQL code as you build a statement. You can use Query Builder to create and execute SELECT statements for tables and views. You can also test queries, and easily adjust your information, before you save. Query Builder does not rely on knowledge of the underlying SQL code.

You can save and reopen queries in Query Builder. Query Builder automatically checks for changes in your tables or columns between the time you save the query and the time you reopen it.

The table below describes the types of queries available in Query Builder:

<table>
<thead>
<tr>
<th>Query Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Building a SELECT Statement</strong></td>
<td>Create, manipulate and execute SELECT Statements for tables and views.</td>
</tr>
<tr>
<td><strong>Building an INSERT Statement</strong></td>
<td>Create and manipulate INSERT Statements for tables.</td>
</tr>
<tr>
<td><strong>Building an UPDATE Statement</strong></td>
<td>Create and manipulate UPDATE Statements for tables.</td>
</tr>
<tr>
<td><strong>Building a DELETE Statement</strong></td>
<td>Create and manipulate DELETE Statements for tables.</td>
</tr>
<tr>
<td><strong>Building a CREATE VIEW Statement</strong></td>
<td>Create and manipulate CREATE VIEW Statements for tables and views.</td>
</tr>
</tbody>
</table>

**Note:** You can execute SELECT statements directly from Query Builder. INSERT, UPDATE, DELETE, and CREATE VIEW statements must be moved to an ISQL Editor for execution.

**Topics**

- [Query Builder Design](#)
- [Using Query Builder](#)
Query Builder Design

Query Builder lets you build DML statements using an intuitive, graphical interface. It offers you a powerful and flexible way to quickly create complex statements without sacrificing time manipulating SQL code. Query Builder lets you add tables or columns, create joins, and change statements within the graphic display. It also lets you have multiple sessions working at the same time.

Query Builder includes many different features to assist you in building and manipulating your query:

- **Query Builder Dialog Boxes**
- **Workspace Windows**
- **Query Builder Toolbar**
- **Tables and Views Shortcut Menus**
- **Tables and Views Keyboard Commands**
Workspace Windows

The Workspace Windows provide a comprehensive view of your data structure and query. The table below describes the Workspace Windows:

<table>
<thead>
<tr>
<th>Pane</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query Builder Explorer Window</td>
<td>Includes two tabs that display selected object details: Tables/Views DML</td>
</tr>
<tr>
<td>SQL Diagram Pane</td>
<td>Displays tables or views included in the current query.</td>
</tr>
<tr>
<td>SQL Statement Pane</td>
<td>Displays the SQL code, and when appropriate, a Results Tab.</td>
</tr>
</tbody>
</table>

Query Builder Explorer Window

The Query Builder Explorer is a separate tree that exposes all the tables and views in your target database. It also displays your current query structure. The Query Builder Explorer includes two tabs that display information about the selected objects:

Tables/Views Tab

The Tables/View Tab displays information about the selected tables or views. You can use the drop-down lists to change your table or view, and when appropriate, the owner. The table below describes each drop-down list on the Tables/Views Tab:

<table>
<thead>
<tr>
<th>List</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>First</td>
<td>Displays all databases for a target Microsoft SQL Server or Sybase ASE.</td>
</tr>
<tr>
<td>Second</td>
<td>Displays all valid owners.</td>
</tr>
</tbody>
</table>

Note: To change your current database, select the new database in the Navigator/Explorer, and then open another Query Builder session. Query Builder prompts you to save the current session prior to opening a new session. For details, see Saving and Reopening Queries.

DML Tab

The DML Tab displays all the basic elements of a query statement in the SQL Statement Tree. You can access any element of the current statement display and perform SQL editing from the SQL Statement Tree.

SQL Diagram Pane

The SQL Diagram Pane displays tables, views, and joins included in the current query. You can manipulate elements of your query, using the mouse functionality, in the SQL Diagram Pane. From the SQL Diagram Pane you can:

- Working with Tables and Views in the SQL Diagram Pane
Workspace Windows

- Joins
- Working with Columns in the SQL Diagram Pane

All changes in the SQL diagram reflect in correct SQL code in the SQL Statement Pane.

**SQL Statement Pane**

The SQL Statement Pane displays the current query SQL code. When you run a query, Query Builder displays results to your query in the SQL Statement Pane. The SQL Statement Pane is divided into two tabs:

**SQL Tab**

The SQL Tab displays the query in progress. It displays each element of your query as you build it, and updates as you do edits such as selecting or deselecting columns, adding clauses, and creating joins. You can open the current statement directly into an ISQL editor or copy it to the clipboard for later use.

**Results Tab**

The Results Tab displays the results of your executed query in the Results grid. To edit data, use the Data editor application from Query Builder. When you begin building a new query, the tab title changes to Old Results until you execute the new query. For details, see Using Data Editor with Query Builder.

**Topics**

- Query Builder
- Creating a Clause Using the SQL Statement Tree
## Query Builder Toolbar

The Query Builder tool bar lets you access commonly used features. The table below describes Query Builder tool bar functionality:

<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy</td>
<td>Copies the current SQL statement to the clipboard.</td>
</tr>
<tr>
<td>Statement Box</td>
<td>Displays the type of statement currently on display in the main workspace window.</td>
</tr>
<tr>
<td>Stop Execution</td>
<td>Stops an executing query.</td>
</tr>
<tr>
<td>Execute</td>
<td>Executes the current SELECT or CREATE VIEW statement. If the button is not available, the statement is not executable.</td>
</tr>
<tr>
<td>New</td>
<td>Adjusts to the target node in the Query Builder Explorer window.</td>
</tr>
<tr>
<td>Edit</td>
<td>Displays, on the DML Tab, the ORDER BY or GROUP BY dialog boxes when target node is selected.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the target object.</td>
</tr>
<tr>
<td>Auto Layout</td>
<td>Resets the main workspace to the auto layout mode.</td>
</tr>
<tr>
<td>Auto Join</td>
<td>Finds and joins, automatically, like items by name.</td>
</tr>
<tr>
<td>Statement Check</td>
<td>Checks query syntax.</td>
</tr>
<tr>
<td>Edit Data</td>
<td>Opens Data Editor.</td>
</tr>
<tr>
<td>Close</td>
<td>Closes the current query.</td>
</tr>
</tbody>
</table>

**Note:** Query Builder adjusts tool availability to match the current query functionality.

Tables and Views Shortcut Menus

Query Builder includes a shortcut menu that lets you manipulate a table or view. The table below describes the table shortcut options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete</td>
<td>Removes the table from the SQL Diagram Pane, and the SQL Statement.</td>
</tr>
<tr>
<td>Title Font</td>
<td>Specifies the table title font for this diagram.</td>
</tr>
<tr>
<td>Column Font</td>
<td>Specifies the column font for this diagram.</td>
</tr>
<tr>
<td>Background Color</td>
<td>Specifies the table background color for this diagram.</td>
</tr>
<tr>
<td>Select Star</td>
<td>Selects every column in the table.</td>
</tr>
<tr>
<td>Select None</td>
<td>Deselects every column in the table.</td>
</tr>
<tr>
<td>Bring to Front</td>
<td>Moves the table to the top layer of the diagram.</td>
</tr>
<tr>
<td>Properties</td>
<td>For more information, see Table Properties.</td>
</tr>
</tbody>
</table>

Note: Your selection applies to all selected tables and views.

Topics

- Query Builder
Tables and Views Keyboard Commands

Query Builder provides a number of keyboard shortcuts that let you quickly construct queries. The table below describes the keyboard commands:

<table>
<thead>
<tr>
<th>Keyboard Command</th>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESCAPE</td>
<td>SQL Diagram Pane</td>
<td>Breaks off a join.</td>
</tr>
<tr>
<td>F5</td>
<td>Query Builder</td>
<td>Refreshes screen and runs Schema Change Detection. In a CREATE VIEW, this key adds the new view to the Table Tree Pane.</td>
</tr>
<tr>
<td>CTRL A</td>
<td>SQL Diagram Pane</td>
<td>Selects all tables and joins in the current diagram.</td>
</tr>
<tr>
<td>F1</td>
<td>Query builder and application</td>
<td>Obtains context sensitive Help.</td>
</tr>
</tbody>
</table>

Topics

- For more information, see Query Builder
Query Builder Dialog Boxes

Query Builder includes a number of dialog boxes to assist you in building and customizing your query.

<table>
<thead>
<tr>
<th>Dialog Box</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statement Properties</td>
<td>Specifies general properties in an individual Query Builder session.</td>
</tr>
<tr>
<td>Table Properties</td>
<td>Specifies column selection and alias names for a table or view.</td>
</tr>
<tr>
<td>Column Properties</td>
<td>Specifies column functionality within SELECT and CREATE VIEW statements.</td>
</tr>
</tbody>
</table>

Statement Properties

The Statement Properties dialog box lets you customize properties in an individual Query Builder session. For example, you can set options to limit the number of rows returned in a query to save execution time, or turn off the auto join function to manually control all joins for an individual query. These properties override the global options set in the Options editor for the current session. For details, see Query Builder Options.

The table below describes the options and functionality of the Statement Properties dialog box.

<table>
<thead>
<tr>
<th>Interface Element</th>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code Generation</td>
<td>Generate Use Database statement</td>
<td>Adds a line of SQL code indicating which database or instance is used in the statement.</td>
<td>Selected</td>
</tr>
<tr>
<td></td>
<td>Generate owner names</td>
<td>Adds a line of SQL code showing the table owner name as part of the query.</td>
<td>Selected</td>
</tr>
<tr>
<td></td>
<td>Include Row Count limits</td>
<td>Includes the output row limit set in the Execution settings.</td>

### Query Builder Dialog Boxes

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto populate views</td>
<td>Lets Query Builder automatically populate views.</td>
<td>Not selected</td>
</tr>
<tr>
<td>Auto Join</td>
<td>Joins indexed columns automatically, and requires indexed columns for joins.</td>
<td>Selected</td>
</tr>
<tr>
<td>Require Indexes</td>
<td>Automatically joins columns with the same data type.</td>
<td>Selected</td>
</tr>
<tr>
<td>Require same data type</td>
<td>Automatically joins columns with the same data type.</td>
<td>Selected</td>
</tr>
<tr>
<td>Syntax Checker</td>
<td>Lets Query Builder check syntax every time an execute statement, refresh or copy statement begins.</td>
<td>Selected</td>
</tr>
<tr>
<td>Run Automatically</td>
<td>Lets Query Builder automatically detect like names and data types and create joins for multiple tables.</td>
<td>Selected</td>
</tr>
<tr>
<td>Display</td>
<td>Lets you set the font, font style, size, and color of column fonts.</td>
<td>Available</td>
</tr>
<tr>
<td>Columns Font</td>
<td>Lets you set the font, font style, size, and color of column fonts.</td>
<td>Available</td>
</tr>
<tr>
<td>Title Font</td>
<td>Lets you set the font, font style, size, and color of table/view title fonts.</td>
<td>Available</td>
</tr>
<tr>
<td>Table Color</td>
<td>Lets you set the background color of your tables in the SQL Diagram Pane.</td>
<td>Available</td>
</tr>
</tbody>
</table>

**Note:** If you set options in the Options editor while Query Builder is running, a warning indicates that you are about to change options or properties. For details, see [Query Builder Options](#).

### Completing the Statement Properties Dialog Box

To complete the Statement Properties dialog box, do the following:

1. On the **Query Builder** menu, click **Statement Properties**.
2. Set options.
3. Click **OK**.

Query Builder saves the options.

### Table Properties

The Tables Properties dialog box lets you set parameters for tables or views in your SQL Diagram. The table below describes the options and functionality on the Table Properties dialog box.
Query Builder Dialog Boxes

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Alias</td>
<td>Creates an alias name for your table.</td>
</tr>
<tr>
<td>Show Datatypes</td>
<td>Shows or hides the datatype for every column in the target table.</td>
</tr>
<tr>
<td>Displayed Columns</td>
<td>Displays columns visible in the SQL Diagram.</td>
</tr>
<tr>
<td>Hidden Columns</td>
<td>Displays columns hidden in the SQL Diagram.</td>
</tr>
<tr>
<td>Hide All</td>
<td>Moves all non selected columns in the table to the Hidden Columns window.</td>
</tr>
<tr>
<td>Display All</td>
<td>Moves all columns in the table to the Displayed Columns window.</td>
</tr>
<tr>
<td>Right Arrow</td>
<td>Moves a target file from Displayed Columns to Hidden Columns.</td>
</tr>
<tr>
<td>Left Arrow</td>
<td>Moves a target file from Hidden Columns to Displayed Columns.</td>
</tr>
</tbody>
</table>

Completing the Table Properties Dialog Box

To complete the Table Properties dialog box, do the following:

1. Double click the target table or view title bar.

OR

Right-click target table or view, and then click Properties.

2. If you only want to hide or display columns in your table, click the arrow button on the table title bar.

3. You can also edit view properties from the Table Properties dialog box.

4. Click OK.

Query Builder saves the changes.

Column Properties

The Column Properties dialog box lets you set properties for individual columns in your SELECT or CREATE VIEW statements. You can set aggregate functions and create an alias for an individual column.

The Column Properties dialog box is not available for INSERT, UPDATE or DELETE statements. The table below describes the options and functions Columns Properties dialog box:
## Interface Element

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tables/Views</td>
<td>Displays all tables and views in the SQL Diagram Pane.</td>
</tr>
<tr>
<td>Aggregate</td>
<td>Specifies aggregate options for the target column. AVG - An average is taken for a column with an int or numeric datatype. COUNT - Returns the number of rows which contain data for the target column. MAX - Returns the highest number in a row in the column. MIN - Returns the lowest number in a row in the column. SUM - Returns the sum of the target column in all rows which contain data. This function is only operable on int or numeric datatypes.</td>
</tr>
<tr>
<td>Alias</td>
<td>Displays the alias name for the target column. Lets you type the name of the alias. NOTE: Query Builder displays the results of an aggregate column without a column name unless you create an alias for that column.</td>
</tr>
<tr>
<td>Available Columns</td>
<td>Displays all available columns in the target table or view.</td>
</tr>
<tr>
<td>Selected Columns</td>
<td>Displays all selected columns in the target table or view. To create an aggregate function or alias for a different column, select target column, select an aggregate function, and then type the name of the alias.</td>
</tr>
<tr>
<td>Select All</td>
<td>Moves all columns in the Available Columns box to the Selected Columns box.</td>
</tr>
<tr>
<td>Clear All</td>
<td>Moves all columns in the Selected Columns box to the Available Columns box.</td>
</tr>
<tr>
<td>Right Arrow</td>
<td>Moves target column in the Available Columns box to the Selected Columns box.</td>
</tr>
<tr>
<td>Left Arrow</td>
<td>Moves target column in the Selected Columns box to the Available Columns box.</td>
</tr>
<tr>
<td>Select List Statement</td>
<td>Displays the current query.</td>
</tr>
</tbody>
</table>

## Completing the Column Properties Dialog Box

To complete the Column Properties dialog box, do the following:

1. On the **SQL Statement Tree**, double-click target column.
2. Select options.
3. Click **OK**.

## Join Properties

Query Builder lets you edit joins with the Join editor. You can edit join parameters in a SELECT, UPDATE, DELETE, and CREATE VIEW Statement.

The table below describes the options and functionality on the Join dialog box.
Query Builder Dialog Boxes

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>From Table Column</td>
<td>The primary column in the join.</td>
</tr>
<tr>
<td>To Table Column</td>
<td>The secondary column in the join.</td>
</tr>
<tr>
<td>Select the join relation</td>
<td>Click the target join operator. If it is not equals, the operator displays on</td>
</tr>
<tr>
<td>operator</td>
<td>the join in the SQL Diagram Pane.</td>
</tr>
<tr>
<td>Join Type: Inner</td>
<td>Click to make the join an inner join. Aggregates are only available for</td>
</tr>
<tr>
<td></td>
<td>inner joins.</td>
</tr>
<tr>
<td>Join Type: Left Outer</td>
<td>Click to make the join a left outer join.</td>
</tr>
<tr>
<td>Join Type: Right Outer</td>
<td>Click to make the join a right outer join.</td>
</tr>
</tbody>
</table>

**Note:** For IBM DB2 for Linux, Unix, and Windows and IBM DB2 for z/OS and OS/390 servers, there is an additional join object in the SQL Statement Tree. The Join On node displays join relations between columns in IBM DB2 for Linux, Unix, and Windows and IBM DB2 for z/OS and OS/390 tables and views.

**Completing the Join Dialog Box**

To complete the Join dialog box, do the following:

1. In the SQL Diagram Pane, right-click the target join, and then click Properties.

OR

In the SQL Diagram Pane, double-click the target join.

OR

On the SQL Statement Tree, expand the Where and And nodes, and then double-click the target join.

2. Select options.

3. Click OK.

**Topics**

- Query Builder
Using Query Builder

Query Builder provides a visual display of your queries as you construct them. You can run Query Builder against any registered datasource. Query Builder lets you build five separate types of queries simultaneously:

- Building a SELECT Statement
- Building an INSERT Statement
- Building an UPDATE Statement
- Building a DELETE Statement
- Building a CREATE VIEW Statement

You can execute a SELECT statement from Query Builder. To execute an INSERT, UPDATE, DELETE, and CREATE VIEW statement, copy them to an ISQL Editor. You can also copy the statements to the clipboard for later use in the ISQL Editor.

Query Builder also lets you save a statement at any time so that you can open them later for editing or execution. Saving and Reopening Queries.

You can open Query Builder with multiple tables or views with the same or different owners. If you open tables or views with different owners, Query Builder displays “All Owners” in the Owner drop-down list. You can start multiple Query Builder sessions. You can use different tables and views for each query. You can also toggle back and forth among each of the queries. For more information, see Working with Tables and Views in the SQL Diagram Pane.

You can save and reopen queries in Query Builder. Query Builder automatically checks for changes in your database or instance between the time you save the query and the time you reopen it with the Schema Change detection component.

Query Builder is integrated with Data editor so you can edit data in real time and then continue to build your query with the new information embedded in the query. For details, see Saving and Reopening Queries.

Main Steps in Using Query Builder

To use Query Builder, do the following:

- Selecting a Database
- Selecting a Statement
- Selecting Tables and Views
- Selecting Columns

**Note:** You can start Query Builder directly from a table or view which automatically selects the instance or database which contains that table or view.

1. On the Tools menu, click Query Builder.

Query Builder opens.

**Selecting a Database**

To create an SQL statement, first select an instance or database.

**Note:** You can start Query Builder directly from a table or view which automatically selects the database which contains that table or view.

If you are working with Microsoft SQL Server or Sybase ASE, Query Builder provides two drop-down lists. The first drop-down list displays all available databases for the target server. The second drop-down list displays owners.

If you are working with Oracle, IBM DB2 for z/OS and OS/390 or IBM DB2 for Linux, Unix, and Windows the first drop-down list is unavailable.

**Note:** You can start Query Builder directly from a table or view which automatically selects the database which contains that table or view.

1. Start Query Builder.
2. In the database drop-down list, click the target instance or database.
3. In the owners drop-down list, select the appropriate owner.

Query Builder is ready for Statement selection.

4. To select different instances or databases while Query Builder is running, on the Tables/Views Tab, in the database drop-down list, click the target instance or database.

The current query clears and a warning prompt is displayed.

5. To save the current query, click **Yes**.

The Save As dialog box opens.
6. To continue without saving, click No.

Selecting a Statement

Query Builder lets you build SELECT, INSERT, UPDATE, DELETE, and CREATE VIEW queries simultaneously.

To select a statement, do the following:

1. On the Query Builder toolbar, click the statement drop-down list, and then click the target statement type.

OR

In the SQL Diagram Pane, right-click, and then click the target statement type.

Selecting Tables and Views

To build a query, open one or more tables or views in the SQL Diagram Pane. For details, see SQL Diagram Pane.

You can use different tables or views for each type of query.

Tip: For multiple tables: Press SHIFT+click for adjacent tables or CTRL+click for nonadjacent tables. You can also drag the bounding line with your pointer to select multiple tables.

To select a Table or View, do the following:

1. In the Tables/Views Tab, drag the target table or view to the Diagram Pane.

OR

In the Tables/Views Tab, click target table or view and then, on the Query Builder toolbar, click Add.

OR

In the Tables/Views Tab, right-click target table or view, and then click Add.

Query Builder displays the target table(s) and view(s) in the SQL Diagram Pane.

Selecting Columns

You must select at least one column to build a query. Query Builder displays columns in each table in the SQL Diagram window. By default, Query Builder exposes every column in a table. You can select the columns you want to use for your query. Query Builder orders them, in your statement, in the select order.

Query Builder lets you select columns. For details, see:

- SQL Diagram Pane.
You can select an individual column or all columns. Query Builder orders them, in your statement, in the select order. You can reorder columns after you set them in your diagram or statement.

**Selecting Columns in the SQL Diagram Pane**

To select a column in the SQL Diagram Pane, do the following:

1. Select the check box to the left of the target column name.

**Selecting Columns in the SQL Statement Tree**

Query Builder lets you select and set individual properties using the Selected Column Properties Dialog Box. For details, see Column Properties.

**Selecting all Columns**

Query Builder uses columns in statements based on the order of selection. When you select all columns, Query Builder displays the columns in the order they appear in the table.

**Note:** Query Builder lets you select all columns in single or multiple tables.

To select all columns, do the following:

1. On the Query Builder menu, click Select Star.

**Topics**

- Saving and Reopening Queries
- Using Query Builder
Building a Query

Query Builder lets you build SELECT, INSERT, UPDATE, SELECT, and CREATE VIEW statements, which you can run separately or simultaneously, depending on your needs.

To build a Query, do the following:

- Selecting a Database
- Selecting a Statement
- Selecting Tables and Views
- Selecting Columns

Note: You can start Query Builder directly from a table or view which automatically selects the database which contains that table or view.

Query Builder lets you build queries that include both tables and views in the SQL Diagram Pane for SELECT and CREATE VIEW statements. For the INSERT, UPDATE, and DELETE statements, use one or the other object, but you cannot use both.

Once you make your selections, you can edit, restructure, and streamline your query. Query Builder offers many options for streamlining your queries.

Building a SELECT Statement

Query Builder lets you construct and execute simple-to-complex SELECT statements using data from any table or view. You can also create and edit joins for SELECT statements. Query Builder can check your query and warn you if there are syntax errors with the Syntax Checker.

To build a SELECT statement, do the following:

1. On the Tools menu, click Query Builder.

The Query Builder opens.

2. In the statement drop-down list, click SELECT.

3. In the Table Tree Pane, select target table(s) or view(s) and move them to the SQL Diagram Pane.

4. In the target table or view, click target column(s), or click Select Star to select every column.

5. To check syntax, click Check.

6. To copy the statement, click Copy.

7. To execute the statement, click Execute.

Copying a SELECT Statement from the SQL Statement Pane
Building a Query

To copy any part of a statement from the SQL Statement Pane, do the following:

1. Open Query Builder, then begin a new SELECT statement.

OR

Open an existing SELECT statement.

2. In the SQL Statement Pane, select all, or the target portion of the statement.

3. On the Query Builder tool bar, click Copy.

OR

In the SQL Statement Pane, right-click, and then click Copy.

Query Builder makes the target statement portion available on the clipboard.

Building an INSERT Statement

Query Builder lets you construct and execute simple-to-complex INSERT statements using data from any table. To execute an INSERT statement, copy it to an ISQL Editor. You can also copy the statement to the clipboard for later use in the ISQL Editor.

Query Builder also lets you save your statement at any time so that you can open it later for editing or execution. For details, see Saving and Reopening Queries.

Building an INSERT Statement

To build an INSERT Statement, do the following:

1. On the Tools menu, click Query Builder.

The Query Builder opens.

2. In the statement drop-down list, click INSERT.

3. In the Table Tree Pane, select target table, and move it to the SQL Diagram Pane.

4. In the target table, click target column(s).

Copying an INSERT Statement from the SQL Statement Pane

To copy any part of a statement from the SQL Statement Pane, do the following:

1. Open Query Builder, then begin a new INSERT statement.

OR

Open an existing INSERT statement.

2. In the SQL Statement Pane, select all, or the target portion of the statement.

3. On the Query Builder tool bar, click Copy.
Building a Query

OR

In the SQL Statement Pane, right-click, and then click Copy.

Query Builder makes the target statement portion available on the clipboard.

Building an UPDATE Statement

Query Builder lets you construct and execute simple-to-complex UPDATE statement using data from any table. To execute an UPDATE statement, copy it to an ISQL Editor. You can also copy the statement to the clipboard for later use in the ISQL Editor.

Query Builder also lets you save your statement at any time so that you can open it later for editing or execution. For details, see Saving and Reopening Queries.

Building an UPDATE Statement

To build an UPDATE statement, do the following:

1. On the Tools menu, click Query Builder.

The Query Builder opens.

2. In the statement drop-down list, click UPDATE.

3. In the Table Tree Pane, select target table and move it to the SQL Diagram Pane.

4. In the target table, click target column(s).

Copying an UPDATE Statement from the SQL Statement Pane

To copy any part of a statement from the SQL Statement Pane, do the following:

1. Open Query Builder, then begin a new UPDATE statement.

OR

Open an existing UPDATE statement.

2. In the SQL Statement Pane, select all, or the target portion of the statement.

3. On the Query Builder tool bar, click Copy.

OR

In the SQL Statement Pane, right-click, and then click Copy.

Query Builder makes the target statement portion available on the clipboard.

Building a DELETE Statement

Query Builder lets you construct DELETE statements using data from any table. Query Builder displays a Confirmation Option Message box when you create a DELETE
statement. You can set the **Statement Properties** dialog box to display or hide this message when creating a DELETE statement. For details, see [Statement Properties](#).

To execute a DELETE statement, copy it to an ISQL Editor. You can also copy the statement to the clipboard for later use in the ISQL Editor.

Query Builder also lets you save your statement at any time so that you can open it later for editing or execution. For details, see [Saving and Reopening Queries](#).

### Building a DELETE Statement

To build a DELETE statement, do the following:

1. On the Tools menu, click Query Builder.
   
   The Query Builder opens.

2. In the statement drop-down list, click **DELETE**.

3. In the **Table Tree** Pane, select target table, and move it to the **SQL Diagram Pane**.

### Copying a DELETE Statement from the SQL Statement Pane

To copy any part of a statement from the SQL Statement Pane, do the following:

1. Open Query Builder, then begin a new DELETE statement.

   OR

2. Open an existing DELETE statement.

   2. In the SQL Statement Pane, select all, or the target portion of the statement.

   3. On the Query Builder tool bar, click Copy.

   OR

   In the SQL Statement Pane, right-click, and then click Copy.

Query Builder makes the target statement portion available on the clipboard.

### Building a CREATE VIEW Statement

Query Builder lets you construct and execute simple-to-complex CREATE VIEW statements using data from any table or view. You can also copy the statement to the clipboard for later use in the ISQL Editor.

Query Builder also lets you save your statement at any time so that you can open it later for editing or execution. For details, see [Saving and Reopening Queries](#).

To build a CREATE VIEW statement, do the following:

1. On the Tools menu, click Query Builder.

   The Query Builder opens.
2. In the statement drop-down list, click CREATE VIEW.

3. In the Table Tree Pane, select target table or view and move it to the SQL Diagram Pane.

**Note:** Query Builder supports multiple tables and views in a CREATE VIEW statement.

4. In the target table or view, click the target column(s).

5. To check syntax, click Check.

6. To copy the statement, click Copy.

7. To execute the CREATE VIEW Statement, click the SQL Statement Pane, and then press any key.

Query Builder opens the Edit SQL dialog box.

8. Click OK.

**Caution:** If you have used this method previously, and you selected the Please do not show me this dialog again check box, on the Edit SQL dialog box, Query Builder does not display the Edit SQL dialog box. It pastes your statement directly to the ISQL Editor.

The ISQL Editor opens.

9. In the ISQL Editor, on the line, CREATE VIEW NAME AS, replace the word NAME with a name for your view.

10. On the tool bar, click Execute.

The CREATE VIEW query executes.

11. To close the Editor, click Close.

The ISQL Editor save message opens.

12. Click No.

13. To add the view to the table tree, on the Query Builder menu, click Refresh.

Query Builder adds the view to the Table Tree Pane.

**Copying a CREATE VIEW Statement from the SQL Statement Pane**

To copy any part of a statement from the SQL Statement Pane, do the following:

1. Open Query Builder, then begin a new CREATE VIEW statement.

**OR**

Open an existing CREATE VIEW statement.

2. In the SQL Statement Pane, select all, or the target portion of the statement.

3. On the Query Builder tool bar, click Copy.
Building a Query

OR

In the SQL Statement Pane, right-click, and then click Copy.
Query Builder makes the target statement portion available on the clipboard.

Working with Tables and Views in the SQL Diagram Pane

Query Builder lets you organize your tables and views in the SQL Diagram Pane. You can also customize appearance, change visual aspects, and adjust layout while continuing to manufacture a query. You can resize or customize a selected table and view, or move them to the front or back of the diagram. The key symbol indicates a column that is indexed or participates in a primary key.

- Selecting and Deselecting Tables and Views
- Moving Tables and Views
- Moving Additional Tables and Views to the SQL Diagram Pane
- Deleting a Table or View

Query Builder can automatically dictate a layout in the SQL Diagram Pane using the Auto Layout button. For details, see Auto Layout.

Selecting and Deselecting Tables and Views

You can select tables and views in the SQL Diagram Pane. You can make changes to more than one table or view simultaneously by selecting multiple tables or views.

To select and deselect Tables and Views, do the following:

1. To select a table, click the table title bar.
2. To select more than one table, drag the pointer to enclose all target tables with the bounding line.

Query Builder selects all target tables; none have handles.

3. To select all tables, in the SQL Diagram, right-click, and then click Select All.
4. Click the SQL Diagram workspace to deselect all tables.

Moving Tables and Views

Query Builder lets you move tables and views in the SQL Diagram Pane. It also moves selections and joins with the tables and views.

To move Tables and Views, do the following:

1. To move a table or view, drag the title bar to the target location.

Note: If you select more than one table or view, Query Builder moves all selected tables and views and any joins with the pointer.
Moving Additional Tables and Views to the SQL Diagram Pane

Query Builder sets tables and views in your statement in the order that you move them to the SQL Diagram Pane. Tables and views moved into the Diagram Pane appear first in your statement, including all joins connecting that table. To change the order of tables, move them back into the Table Tree and re-select them in the order in which you would like to join them.

**Moving Additional Tables or Views**

To move additional tables or views, do the following:

1. Click the target table or view and drag it to the Diagram Pane.

For multiple tables or views: Use SHIFT+click for adjacent tables or views or use CTRL+click for non-adjacent tables and views.

OR

Click the target table or view, and then on the Query Builder tool bar, click Add.

OR

Right-click the target table or view, and then click **Add**.

For multiple tables or views: Use SHIFT+click for adjacent tables or views or use CTRL+click for non-adjacent tables and views.

**Note:** Moving a table or view to the SQL Diagram Pane is not available while a query is executing.

Deleting a Table or View

To delete tables from the SQL Diagram Pane, do the following:

1. Right-click the target table or view, and then click Delete.

OR

In the SQL Diagram, click target table or view, and then on the Query Builder tool bar, click Delete.

OR

In the SQL Diagram, right-click the target table or view, and then click Delete.

Query Builder deletes the table from the SQL Diagram, SQL Statement, and SQL Statement Tree.
Working with Columns in the SQL Diagram Pane

You can customize queries by selecting and deselecting columns in the SQL Diagram Pane. You can customize columns using the Selected Column Properties dialog box. For details, see Column Properties.

Selecting and deselecting columns

You can select and deselect columns in the SQL Diagram. Query Builder lets you select and deselect individual columns or all columns. Your results reflect the order of selection. You can change the order of columns after you set them in your diagram or statement.

Tip: You can also select, re-order and deselect columns in the SQL Statement Tree. For more information, see Selecting Columns in the SQL Statement Tree.

Selecting Individual Columns

To select individual columns, do the following:

1. To select a column, in the SQL Diagram, select the check box to the left of the target column name.

Deselecting Individual Columns

To deselect individual columns, do the following:

1. To deselect a column, in the SQL Diagram, select the check box to the left of the target column name.

Note: When you clear the columns, Query Builder deletes the columns and any sub clauses from the SQL Statement Pane and SQL Statement Tree.

Selecting All Columns

To select all columns, do the following:

1. On the Query Builder menu, click Select Star.

Note: Query Builder uses columns in statements based on the order of selection. When you select all columns, Query Builder displays the columns as they appear in the table.

Deselecting All Columns

To deselect all columns, do the following:

1. On the Query Builder menu, click Select None.
Query Builder adds or removes selected columns from the SQL Statement Tree and the SQL Statement Pane.

Selecting ALL or DISTINCT Columns

Selecting ALL or DISTINCT columns is a way to filter data in your query. Selecting ALL columns means all rows displays results in the grid regardless of duplication in non-primary key columns. The DISTINCT column function is a query process that limits duplicate data in non-primary key columns to rows with the first iteration of any identical data. For example, if there are two identical addresses for different last names, and the column with a primary key does not participate in the query, only the row with the first instance of the address displays in the results of the query.

To select ALL or DISTINCT columns, do the following:

1. In the Statement Tree pane, right-click the ALL or DISTINCT node, click Properties, and then select the ALL or DISTINCT check box.

OR

In the Statement Tree pane, double click the ALL or DISTINCT node. Query Builder toggles to the opposite function.

Note: You can change between ALL or DISTINCT at any time prior to executing or copying a query.
Join Joins let you distill the information in your database to a usable form. Query Builder lets you create, manipulate, and edit work with joins without requiring knowledge of the underlying SQL code. Query Builder lets you create any type of join for SELECT and CREATE VIEW Statements. You can create self joins for UPDATE or DELETE Statements. You cannot create joins for INSERT Statements.

Query Builder includes four types of joins. The table below describes joins and their availability in Query Builder:

<table>
<thead>
<tr>
<th>Join</th>
<th>Statement Availability</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inner Joins</td>
<td>SELECT, CREATE VIEW, DELETE, UPDATE</td>
<td>Returns data from the joined tables that match the query’s join criteria and set a relation between tables or views. Inner joins return results where the join condition is true.</td>
</tr>
<tr>
<td>Left Outer Joins</td>
<td>SELECT, CREATE VIEW</td>
<td>Returns all data from the primary table and data from the joined tables that match the query's join criteria and set a join relation operator from a column in a primary table or view to a column in a secondary table or view.</td>
</tr>
<tr>
<td>Right Outer Joins</td>
<td>SELECT, CREATE VIEW</td>
<td>Returns all data from the primary table and data from the joined tables that match the query’s join criteria and set a join relation operator from a column in a secondary table or view to a column in a primary table or view.</td>
</tr>
<tr>
<td>Self Joins</td>
<td>SELECT, CREATE VIEW</td>
<td>Set a relation between columns in the same table.</td>
</tr>
</tbody>
</table>

In the Query Builder SQL Diagram Pane, you can create, edit, and delete joins. You can edit joins in the Join dialog box. For details, see Editing Joins.

You can set Query Builder options, in the Options editor, to automatically create joins. For details, see Query Builder Options.

Joins are the way you can filter data in relational databases. Query Builder lets you change the types of joins between tables, views and columns. It is important that you have some knowledge of the data in your tables, and the datatypes for each column. This information helps you frame a better query, and filter your data for maximum effect.

Inner Joins

Inner joins are the most common types of joins for SELECT statements. An inner join returns information from two tables where the relation between two target columns is true for both columns.

The join operand determines the relation results, for example, if the join operand is equals, then identical data, in two columns, is the only result. If the join operand is not equals, Query Builder only returns data that is different between two columns.
Joins

For example, if you have an inner join matching territory numbers between the table dbo.Managers and dbo.Clients, running the query returns all Managers and Clients with matching territory numbers:

Query Builder displays the following results from this query with an inner join

**Note:** Query Builder displays results of columns in the order of selection. You can reorder columns by deselecting and selecting in the SQL Diagram Pane, the Selected Columns Properties dialog box, or the SQL Statement Tree.

**Left Outer Joins**

Left outer joins bring back a different data set than **Inner Joins**. Left outer joins retrieve all the data in columns selected from the primary table, and only matching data from the joined or secondary table.

For example, in the same pair of tables, a left inner join from dbo.Managers to dbo.Clients, where the columns Current Territory and Territory are joined, displays different results.

**Note:** There is one additional manager who does not have a client, but because a left outer join includes all data from selected columns in the primary table, the last entry in the illustration is displayed.

**Right Outer Joins**

Right outer joins return opposite results from **Left Outer Joins**. In a right outer join, you are asking for all the information in the secondary table’s column, and the join operator’s matching information from the primary table.

For example, in the same set of data we used in the left outer join example, a right outer join returns all clients from dbo.Client, and only managers who match territory numbers, in the joined column.

**Note:** The managers are the same as the first, inner join, but a right outer join returns the additional clients without matching managers.

**Self Joins**

A self join is a join within a single table. Query Builder lets you return specific information from a single table using a self join.

For example, in our example table, there is a column for the number of clients and another column with the goal client total for a territory.

A self join can ascertain which managers are reaching their quota. Notice that the join relation operator in the example is greater than or equal to, which shows managers exceeding quota as well.
Adding and Deleting a Join in the SQL Diagram Pane

Query Builder lets you add and delete joins. This method adds a WHERE clause in your query. You can join different tables and or views in a SELECT or CREATE VIEW statement.

Adding a Join

To add a Join, do the following:

1. In the SQL Diagram Pane, drag the target column to the second column.

Query Builder displays both a line joining the two columns in the SQL Diagram Pane and the corresponding SQL code in the SQL Statement Pane.

Removing a Join

Query Builder lets you remove joins from your query. Query Builder automatically deletes joins from the query in the SQL Statement Pane, when you remove them from the SQL Diagram Pane.

To remove a join, do the following:

1. Click the target join, and then on the Query Builder tool bar, click Delete.

OR

Right-click the target join, and then click Delete.

Query Builder deletes the Join.

Editing Joins

Query Builder lets you edit joins with the Join editor. You can edit join parameters in a SELECT, UPDATE, DELETE, and CREATE VIEW Statement.

The table below describes the options in the Join dialog box:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>From Table Column</td>
<td>The primary column in the join.</td>
</tr>
<tr>
<td>To Table Column</td>
<td>The secondary column in the join.</td>
</tr>
<tr>
<td>Select the join relation</td>
<td>Click the target join operator. If it is not equals, the operator displays</td>
</tr>
<tr>
<td>operator</td>
<td>on the join in the SQL Diagram Pane.</td>
</tr>
<tr>
<td>Join Type: Inner</td>
<td>Click to make the join an inner join. Aggregates are only available for</td>
</tr>
<tr>
<td></td>
<td>inner joins.</td>
</tr>
<tr>
<td>Join Type: Left Outer</td>
<td>Click to make the join a left outer join.</td>
</tr>
<tr>
<td>Join Type: Right Outer</td>
<td>Click to make the join a right outer join.</td>
</tr>
</tbody>
</table>

**Completing the Join Dialog Box**

1. In the SQL Diagram Pane, right-click the target join, and then click Properties.

OR

In the SQL Diagram Pane, double-click the target join.

OR

On the SQL Statement Tree, expand the Where and And nodes, and then double-click the target join.

Query Builder opens the Join dialog box.

**Note:** For IBM DB2 for Linux, Unix, and Windows and IBM DB2 for z/OS and OS/390 servers, there is an additional join object in the SQL Statement Tree. The Join On node displays join relations between columns in IBM DB2 for Linux, Unix, and Windows and IBM DB2 for z/OS and OS/390 tables and views.

**Changing a Join Color**

Query Builder lets you change the color at a join in the SQL Diagram Pane. Complex statements using many tables and multiple joins can be easier to view if joins have different colors.

To change the color of a join, do the following:

1. Right-click the target join, and then click Color.

Query Builder opens the Color dialog box.

2. In the Basic colors grid, click a target color

OR

Click Define Custom Colors, then create a custom color.
**Note:** Query Builder lets you save custom colors for the current color. Click Add to Custom Color to have the option of using that color for your queries.

3. Click OK.

### Auto Layout

The Auto Layout function displays tables and views in the SQL Diagram Pane. It makes the best use of the available area in the SQL Diagram Pane by placing your tables and views in the most efficient manner.

If the automatic join function is on, Query Builder displays all joins between columns in your diagram. Query Builder lets you run the automatic layout function any time you have tables or views in the SQL Diagram Pane.

#### Using Auto Layout

To use Auto Layout, do the following:

1. On the Query Builder menu, click Auto Layout.

Query Builder organizes your tables in the SQL Diagram Pane.

### Topics

- [Auto Joins](#)

#### Auto Joins

Query Builder includes an automatic join function that displays joins between selected tables and views in the SQL Diagram Pane. The Auto Join function seeks columns with the same name and data type. You can set global automatic join parameters in the Options Editor.

You can use the Statement Properties Editor to set local join parameters for the current Query Builder session without changing the global parameters.

#### Using Auto Join

To use Auto Join, do the following:

1. On the Query Builder menu, click Auto Join.

Query Builder joins columns in the SQL Diagram Pane.

### Topics

- [Statement Properties](#)
Creating a Clause Using the SQL Statement Tree

Query Builder lets you build more detailed WHERE, ORDER BY, GROUP BY, and HAVING clauses using the SQL Statement Tree. Query Builder lets you add clauses to SELECT, UPDATE, DELETE, and CREATE VIEW statements.

**Note:** Query Builder does not support clauses for INSERT statements.

For more information, see the following topics:

- Creating a WHERE Clause
- Deleting a WHERE Clause
- Creating an AND Clause in a WHERE Clause
- Deleting an AND Clause
- Inserting an AND or OR Clause
- Deleting an OR Clause
- Creating an ORDER BY Clause
- Changing the Sort Order in an ORDER BY Clause
- Deleting an ORDER BY Clause
- Creating a GROUP BY Clause
- Deleting a GROUP BY Clause
- Creating a HAVING Clause
- Deleting a HAVING Clause

**Creating a WHERE Clause**

Query Builder lets you create a WHERE clause from the SQL Statement Tree which automatically displays in your query.

**Note:** Any additional WHERE clauses are displayed as HAVING clauses.

The table below describes the options and functionality on the Where dialog box.
Creating a Clause Using the SQL Statement Tree

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand (Left)</td>
<td>Lets you click the target column for the first part of your WHERE clause. NOTE: Query Builder lists every column in all tables in the SQL Diagram in the Operand lists.</td>
</tr>
<tr>
<td>Operator</td>
<td>Lets you select the target operator.</td>
</tr>
<tr>
<td>Operand (Right)</td>
<td>Lets you click the target column for the second part of your WHERE clause. Query Builder automatically writes the query language in the Statement option box.</td>
</tr>
</tbody>
</table>

**Note:** Query Builder does not display clause phrases created from the SQL Statement Tree in the SQL Diagram Pane.

**Creating a WHERE Clause**

To Create a WHERE clause, do the following:

1. Click the WHERE node, and then on the Query Builder tool bar, click New.

OR

Right-click the WHERE node, and then click New.

**Deleting a WHERE Clause**

To delete a WHERE clause, do the following:

1. Expand the AND node, and then on the Query Builder tool bar, click Delete.

OR

Expand the AND node, right-click target column and then click Delete.

Query Builder deletes the target clause and removes it from the SQL Statement Pane.

**Creating an AND Clause in a WHERE Clause**

Query Builder lets you add an AND clause from the SQL Statement Tree which automatically displays in your query.

The table below describes the options and functionality on the Where dialog box.
Creating a Clause Using the SQL Statement Tree

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand (Left)</td>
<td>Lets you click the target column for the first part of your WHERE clause.</td>
</tr>
<tr>
<td>Operator</td>
<td>Lets you select the target operator.</td>
</tr>
<tr>
<td>Operand (Right)</td>
<td>Lets you click the target column for the second part of your WHERE clause.</td>
</tr>
<tr>
<td></td>
<td>Query Builder automatically writes the query language in the Statement option box.</td>
</tr>
<tr>
<td>New Button</td>
<td>Click to clear your selections but remain in the Where dialog box. Query Builder adds another AND clause to your query.</td>
</tr>
</tbody>
</table>

To open the Where dialog box, do the following:

1. Click the AND node, and then on the Query Builder tool bar, click New.

OR

Expand the WHERE node, right-click the AND node, and then click New.

**Deleting an AND Clause**

To delete an AND clause, do the following:

1. Expand the AND node, click target column, and then on the Query Builder tool bar, click Delete.

OR

Expand the AND node, click target column, and then on the keyboard press DELETE.

OR

Expand the AND node, right-click the target column, and then click Delete.

Query Builder deletes the target clause and removes it from the SQL Statement Pane.

**Inserting an AND or OR Clause**

Query Builder lets you insert an AND or an OR WHERE clause from the SQL Statement Tree which automatically displays in your query. Query Builder lets you insert AND or OR clauses at any appropriate point in the SQL Statement Tree.

The table below describes the options and functionality on the Where dialog box.
Creating a Clause Using the SQL Statement Tree

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand (Left)</td>
<td>Lets you click the target column for the first part of your WHERE clause.</td>
</tr>
<tr>
<td>Operator</td>
<td>Lets you select the target operator.</td>
</tr>
<tr>
<td>Operand (Right)</td>
<td>Lets you click the target column for the second part of your WHERE clause. Query Builder automatically writes the query language in the Statement option box.</td>
</tr>
<tr>
<td>New Button</td>
<td>Click to clear your selections but remain in the Where dialog box. Query Builder adds another AND clause to your query.</td>
</tr>
</tbody>
</table>

To insert an AND or OR Clause, do the following:

1. On the SQL Statement Tree, expand the WHERE node, right-click the target AND node, then click Insert, and then click And or Or.

Deleting an OR Clause

To delete an OR clause, do the following:

1. Expand the OR node, and then on the Query Builder tool bar, click Delete.

OR

Expand the OR node, right-click the target column and then click Delete.

Query Builder deletes the target clause and removes it from the SQL Statement Pane.

Creating an ORDER BY Clause

Query Builder lets you create an ORDER BY clause from the SQL Statement Tree which automatically displays in your query.

The table below describes the Order By Columns dialog box.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available Columns</td>
<td>Select target column(s) and click the right arrow. Query Builder moves target column from the Available Columns list to the Order By Columns list. NOTE: Query Builder sorts query results based on the order that columns are placed in the ORDER BY clause.</td>
</tr>
<tr>
<td>Order</td>
<td>Lets you select the target sort order. ASC - Ascending DESC - Descending Query Builder displays the SQL language in the Order By Statement box.</td>
</tr>
</tbody>
</table>

To open the Order By Columns dialog box, do the following:

1. On the SQL Statement Tree, click the ORDER BY node, and then on the Query Builder tool bar, click Properties.

OR
On the SQL Statement Tree, right-click the ORDER BY node, and then click Properties.

**Changing the Sort Order in an ORDER BY Clause**

To quickly change the sort order of a column in a query, do the following:

1. On the SQL Statement Tree, expand the ORDER BY node, and then double-click the target column.

OR

On the SQL Statement Tree, expand the ORDER BY node, then right-click the target column, and then click Properties.

Query Builder opens the Order dialog box.

2. Click the target sort order, and then click OK.

Query Builder appends the Order By clause for target column with the appropriate sort order in the SQL Statement Pane.

**Deleting an ORDER BY Clause**

To delete an ORDER BY clause, do the following:

1. Expand the ORDER BY node, and then on the Query Builder tool bar, click Delete.

OR

Expand the ORDER BY node, right-click the target column, and then click Delete.

Query Builder deletes the target clause and removes it from the SQL Statement Pane.

**Creating a GROUP BY Clause**

The table below describes the options and functionality on the Group By Columns dialog box.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selected Columns</td>
<td>Select target column(s) and click the right arrow. Or click the Select All button. Query Builder moves target column from the Selected Columns list to the Group By Columns list. NOTE: Query Builder sorts query results based on the order that columns are placed in the ORDER BY clause.</td>
</tr>
<tr>
<td>Clear All Button</td>
<td>Click to move target column from the Group By Columns list to the Selected Columns list. Query Builder displays the SQL language in the Group By Statement window.</td>
</tr>
</tbody>
</table>

**Creating a GROUP BY Clause**
To create a GROUP BY clause from the SQL Statement Tree which automatically displays in your query, do the following:

1. On the SQL Statement Tree, double-click the GROUP BY node.

OR

On the SQL Statement Tree, right-click the GROUP BY node, and then click New.

Query Builder adds all the selected columns in your table(s) to the GROUP BY node in the SQL Statement Tree, and to the appropriate location in the SQL Statement Pane.

2. On the GROUP BY node, double-click any column.

OR

On the GROUP BY node, click any column, then on the Query Builder menu, click New.

OR

On the GROUP BY node, right-click any column, then click Properties.

Deleting a GROUP BY Clause

To delete a GROUP BY clause, do the following:

1. On the SQL Statement Tree expand the GROUP BY node, and then on the Query Builder tool bar, click Delete.

OR

On the SQL Statement Tree Expand the GROUP BY node, right-click the target column, and then click Delete.

Query Builder deletes the target clause and removes it from the SQL Statement Pane.

Creating a HAVING Clause

A HAVING clause is a type of WHERE clause. It filters additional information from your tables. Query Builder lets you create a HAVING clause from the SQL Statement Tree which automatically displays in your query. Query Builder lists every column in all tables in the SQL Diagram in the Operand lists. Query Builder displays the datatype of a column in the operand boxes.

The table below describes the options and functionality on the Having dialog box.
Creating a Clause Using the SQL Statement Tree

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand (Left)</td>
<td>Lets you click the target column for the first part of your HAVING clause.</td>
</tr>
<tr>
<td>Operator</td>
<td>Lets you select the target operator.</td>
</tr>
<tr>
<td>Operand (Right)</td>
<td>Lets you click the target column for the second part of your HAVING clause. Query Builder automatically writes the query language in the Statement option box.</td>
</tr>
<tr>
<td>New Button</td>
<td>Click to clear your selections but remain in the Having dialog box. Query Builder adds another AND clause to your query.</td>
</tr>
</tbody>
</table>

**Note:** Query Builder does not display clause phrases created from the SQL Statement Tree in the SQL Diagram Pane.

To create a HAVING clause, do the following:

1. On the SQL Statement Tree, expand the **HAVING** node, and then expand the **And** node. If there is not a join listed on the **And** node, double-click **And**. If there is a join listed, use the shortcut option below.

OR

On the SQL Statement Tree, right-click the **HAVING** node, and then click New.

**Deleting a HAVING Clause**

To delete a HAVING clause, do the following:

1. On the SQL Statement Tree expand the HAVING node, and then on the Query Builder tool bar, click Delete.

OR

On the SQL Statement Tree expand the HAVING node, right-click the target column, and then click Delete.

Query Builder deletes the target clause and removes it from the SQL Statement Pane.

**Changing Tables and Columns Location in the SQL Statement Tree**

Query Builder lets you move tables and columns on the SQL Statement Tree by dragging them to new locations. You can move columns from the AND and OR nodes to an AND or OR node on the WHERE and HAVING clause nodes. Query Builder changes the query in the SQL Statement Pane to match each move. Query Builder moves tables or columns you are dragging below target table or column.

To move a table or column in the SQL Statement Tree, do the following:

1. Expand target node, then drag the target table or column to a new location.
Query Builder makes the appropriate change in the query in the SQL Statement Pane.

**Note:** Query Builder lets you select multiple tables or columns.

2. To move a table or column to the bottom of a node, drag it to the target node.

Query Builder displays the target table or column at the bottom of target node.

**Topics**

- [Selecting Columns in the SQL Statement Tree](#)
Subqueries

Query Builder lets you build subqueries for SELECT and CREATE VIEW statements in the WHERE or HAVING clause. The table below describes the options available for a subquery in Query Builder:

<table>
<thead>
<tr>
<th>Operand</th>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXISTS</td>
<td>Left operand</td>
<td>Specifies data that exists in a column.</td>
</tr>
<tr>
<td>NOT EXISTS</td>
<td>Left operand</td>
<td>Specifies data that does not exist in a column.</td>
</tr>
<tr>
<td>ANY</td>
<td>Right operand</td>
<td>Specifies data satisfying the operator parameters.</td>
</tr>
<tr>
<td>ALL</td>
<td>Right operand</td>
<td>Specifies data satisfying the operator parameters.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Right operand</td>
<td>Specifies data satisfying the operator parameters.</td>
</tr>
</tbody>
</table>

The table below describes the options and functionality on the Where or Having dialog boxes.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand (Left)</td>
<td>Lets you click the target column for the first part of your clause.</td>
</tr>
<tr>
<td>Operator</td>
<td>Lets you select the target operator.</td>
</tr>
<tr>
<td>Operand (Right)</td>
<td>Lets you click the target column for the second part of your clause.</td>
</tr>
<tr>
<td></td>
<td>Query Builder displays the working subquery in the Statement window.</td>
</tr>
<tr>
<td>Subquery</td>
<td>Paste or type the SUBQUERY statement.</td>
</tr>
</tbody>
</table>

To use the WHERE and HAVING dialog boxes to create subqueries, do the following:

1. On the SQL Statement Tree, expand the Where or Having node, and then expand the And node. If there is not a join listed on the And node, double-click And. If there is a join listed, use the shortcut option below.

OR

On the SQL Statement Tree, right-click the Where or Having node, and then click New.

Topics

- Selecting Columns in the SQL Statement Tree
Syntax Checker

The Syntax Checker scans SQL statements for errors. You can check your syntax at any time while you are fashioning a query, or a Procedure or Function. Query Builder can automatically run a syntax check to validate your query when you are executing or copying a statement. The options for the Syntax Checker tool are set in the Options Editor. For details, see Query Builder Options.

**Note:** Query Builder lets you continue with your query even if there are errors detected in the syntax.

Using the Syntax Checker

The table below describes the possible syntax errors the Query Builder Syntax Checker tool displays, in order:

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Does the query contain duplicate aliases?</td>
<td>Query Builder returns an error message when it detects duplicate aliases.</td>
</tr>
<tr>
<td>If the query has a HAVING clause, is there a GROUP BY clause?</td>
<td>Query Builder returns an error message when it detects a HAVING clause without a GROUP BY clause.</td>
</tr>
<tr>
<td>If there are aggregates, or a GROUP BY clause, are all columns in one or the other?</td>
<td>Query Builder returns an error message when it detects an aggregate, or a GROUP BY clause without all columns in one or the other.</td>
</tr>
<tr>
<td>Are there joins against non-indexed columns, or columns not participating in a primary key?</td>
<td>Query Builder returns a warning when it detects a join against a non-indexed column, or a column not participating in a primary key.</td>
</tr>
<tr>
<td>Are there joins between different datatypes?</td>
<td>Query Builder returns a warning when it detects a join between different datatypes.</td>
</tr>
<tr>
<td>Are there cross-products in the query?</td>
<td>Query Builder returns a warning when it detects a cross-product in the query.</td>
</tr>
</tbody>
</table>
Saving and Reopening Queries

You can save and reopen queries in Query Builder. Saving a query saves the SQL Diagram, SQL Statement, and Query Builder Explorer view. Query Builder automatically checks for changes in your database or instance between the time you save the query and the time you reopen it. Query Builder prompts you to save any time you try to close Query Builder, or on application shutdown.

Query Builder runs Schema Change detection any time you set a query to execute, refresh the data, or open a saved query.

You can open multiple saved queries simultaneously.

Saving Queries

To save a query using standard Save and Save As functions, do the following:

1. On the File menu, click Save or Save As.

The Save As dialog box opens.

2. In the File name box, type the name of the query.

Note: By default, the product appends the.qbl extension to Query Builder files. If there is more than one Query Builder session in progress when you save, the file is further appended with an integer, for example.qbl2.

Tip: You can save data in text (*.txt) and XML (*.xml) file formats.

3. Click OK.

The file is saved and the Save As dialog box closes.

Reopening Queries

You can open a query using standard Open functions. Query Builder displays the Query Builder diagram, statement and Query Builder Explorer Pane and it checks the instance or database for schema changes.

The Query Builder Schema Change Detection component checks for:

- Renamed or dropped tables referenced in the query. Renamed tables that have been renamed are considered dropped.
- Renamed or dropped columns referenced in the query. Renamed columns are considered dropped and inserted.
- Columns added or reordered in tables referenced in the query.

If Query Builder detects a change, it opens the Schema Change Detected dialog box. The dialog box displays details of changes to your schema.

Query Builder opens an ISQL Editor with the last saved versions of the SQL statement.
Using Data Editor with Query Builder

SELECT statements. You can open multiple Data Editor sessions so that you can continue to change your data until you find the best match for your query.

**Caution:** Data Editor is a real-time editor. Changes in your data using Data Editor are permanent.

**Opening the Data Editor from Query Builder**

To open the Data Editor from Query Builder, do the following:

1. On the Tools menu, click Query Builder.

Query Builder opens.

2. Select a database or instance. For details, see [Selecting a Database](#).

3. Select a table. For details, see [Selecting Tables and Views](#).

4. Select a column, or columns. For details, see [Selecting Columns](#).

5. On the Query Builder menu, click Edit Data.

The Data Editor opens.

Available DBMS Utility Menu Commands

The **Tools** menu has commands that let you start installed third party utilities.

**Code Workbench**

The Code Workbench reduces the time needed for common day-to-day coding tasks. You can:

- Define auto replacement expressions that can be used to quickly insert commonly used blocks of SQL syntax or commands. For details, see Working with Code Workbench Auto Replace Shortcuts.

- Import and Export Code Workbench settings for client sharing purposes. For details, see Importing and Exporting Settings in Code Workbench.
Working with Code Workbench Auto Replace Shortcuts

The Code Workbench’s Auto Replace feature lets you create a set of shortcuts associated with words, terms, and other character strings commonly used when scripting. Subsequently, when using the SQL Editor, you can have the full character string automatically substituted for the shortcut. For example, if you have a `beg` shortcut set up for the word `begin`, if you type `beg` in the SQL Editor, followed by an activation keystroke (space, tab, or newline), `beg` is replaced by the full word `begin`.

The following topics describe the steps involved in working with Auto Replace shortcuts:

- [Enabling Auto Replace Shortcut Substitution](#)
- [Configuring Auto Replace Shortcuts](#)
- [Using Code Workbench Auto Replace Shortcuts in the ISQL Window](#)
Enabling Auto Replace Shortcut Substitution

Before configured Auto Replace shortcuts can be automatically substituted with the associated full terms, you must first enable the Auto Replace feature.

To enable Auto Replace

1. Select Tools > Code Workbench to open the Code Workbench dialog
2. Select Enable Auto Replace.

Note: If Replace substrings is unselected, only blank-delimited occurrences of auto replace expressions are replaced when an activation event occurs. If selected, all occurrences of auto replace expressions are replaced. For example, consider an Auto Replace expression of BEG that is to be replaced with Begin. With Replace substrings enabled, BEGBEG would be replaced with BeginBegin when an activation event occurs. With Replace substrings disabled, no replacement would occur.

Also see the following topics:

- Working with Code Workbench Auto Replace Shortcuts, for an introduction
- Configuring Auto Replace Shortcuts, for details on setting up shortcuts
- Using Code Workbench Auto Replace Shortcuts in the ISQL Window, for details on invoking Auto Replace.
Configuring Auto Replace Shortcuts

The Code Workbench window’s Auto Replace tab lets you maintain your list of Auto Replace shortcuts.

![Auto Replace tab](image)

Each entry in the list consists of the following:

- The shortcut
- The full term that will be substituted for the shortcut
- The keystroke events that trigger substitution of the term for the shortcut.

To open the Code Workbench and navigate to the Auto Replace tab

To add a shortcut to the list

1. On the Auto Replace tab, click Add.
2. In the Expression box, type a new expression.
3. In the Activation box, press one or more of SPACE, TAB, or NEWLINE to set those as activation keys for this shortcut.
4. In the Replace With box, type the replacement string.
5. Click OK.

The replace expression is now ready for use in the ISQL Window.

To delete a shortcut from the list

1. Select one or more shortcuts from the list, click Delete, and confirm when prompted.
To edit an existing shortcut

1. Select a shortcut from the list, click Edit, and modify the Expression, Activation, or Replace With boxes, as necessary.

Also see the following topics:

- Working with Code Workbench Auto Replace Shortcuts, for an introduction
- Enabling Auto Replace Shortcut Substitution, for details on enabling the feature

Using Code Workbench Auto Replace Shortcuts in the ISQL Window

When Auto Replace is enabled and shortcuts are configured, you can type a replace shortcut in the SQL Editor instead of typing the associated expression. Each time you type one of the activation keys, all shortcuts associated with the activation key are replaced with the defined replacement expression.

Also see the following topics:

- Working with Code Workbench Auto Replace Shortcuts, for an introduction
- Enabling Auto Replace Shortcut Substitution, for details on enabling the feature
- Configuring Auto Replace Shortcuts, for details on setting up shortcuts
Importing and Exporting Settings in Code Workbench

This feature helps standardize your application settings. Code Workbench settings can be exported to an .xml file, sent to another user, and subsequently imported by that user.

Exporting Settings
2. Click Export Settings. Code Workbench opens a Save as dialog box.
3. Use the dialog to specify a location and file name, and then click Save. Code Workbench saves your settings as an .xml file.

Importing Settings
2. Click Import Settings. Code Workbench opens an Open dialog box.
3. Use the dialog to locate and select the .xml file, and then click Open. Code Workbench imports the settings.

Topics
- Code Workbench
Customize (Tools menu)

The Customize dialog lets you specify user interface preferences and set up shortcuts.

Topics

- Customizing the DBArtisan Display

Options (Tools menu)

The Tools menu provides access to the Options Editor, used to configure features and set preferences. For details on using the editor and available options, see Specifying Application Preferences and Feature Options.

Data Editor

The Edit Data function opens the Data Editor. You can use the Data Editor to edit your tables in real-time. The Data Editor supports all editable datatypes and is an alternative way to add, edit, or delete data from your tables.

**Note:** You can use Data Editor within Query Builder to edit data in tables while you create SELECT statements. You can open multiple Data Editor sessions so that you can continue to change your data until you find the best match query. For details, see Query Builder.

The Data Editor includes a Data Editor Filter that lets you select the columns in your table that you want to edit. You must select at least one column to use the Data Editor. The Data Editor Filter is not available for the Query Builder. For more information, see Data Editor Filter.

**Tip:** You can customize Data Editor options in the Options editor. For details, see Data Editor Options.

You can find information about how to access the Data Editor in Using Data Editor.

As you can see in the figure, Data Editor consists of three main parts:

- **Edit Window**
- **SQL Window**
- **Toolbar**
Data Editor Edit Window

Data Editor displays all the information in the target table in the Data Editor Edit Window. You can edit data directly in this window.

Data Editor SQL Window

The Data Editor ISQL Window displays the active SQL statement, which uses the data from the target table.

When appropriate, Data Editor displays a History Tab. The History Tab displays all SQL Statements created in the current session. If there is an error, Data Editor displays an Error Tab. The Error Tab details any errors in data entry encountered during execution.

Data Editor Toolbar

The Data Editor tool bar lets you access commonly used features.

The table below describes the function of each Data Editor tool.
<table>
<thead>
<tr>
<th>Description</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop Button</td>
<td>Stops loading data to the Data Editor. Data Editor displays rows up to the stopping point.</td>
</tr>
<tr>
<td>List of options for the target table</td>
<td>Displays the editing mode for the target table.</td>
</tr>
<tr>
<td>Execute SQL button</td>
<td>Executes the current SQL statement for the target table.</td>
</tr>
<tr>
<td>Insert Record button</td>
<td>Inserts new record for the target table. New records display at the end of the table. For related information, see Default Value Handling.</td>
</tr>
<tr>
<td>Save Current Row button</td>
<td>Saves data in the current selected row. Data Editor prompts to save when you attempt to leave a row in Live mode. For related information, see Default Value Handling.</td>
</tr>
<tr>
<td>Remove Data button</td>
<td>Removes data in target row. Data Editor displays an optional prompt.</td>
</tr>
<tr>
<td>Clear SQL Text button</td>
<td>Clears SQL text from the SQL Statement Pane.</td>
</tr>
<tr>
<td>Undo button</td>
<td>Undoes the most recent operation.</td>
</tr>
<tr>
<td>Redo button</td>
<td>Redoes the most recent operation.</td>
</tr>
<tr>
<td>First Record button</td>
<td>Moves to the first record in the target table.</td>
</tr>
<tr>
<td>Last Record button</td>
<td>Moves to the final record in the target table.</td>
</tr>
<tr>
<td>Filter Data button</td>
<td>Filters table using the target cell as the filter parameter.</td>
</tr>
<tr>
<td>Refresh button</td>
<td>Reloads data for target table</td>
</tr>
<tr>
<td>Calendar button</td>
<td>Sets correct format for target date/time cell. Enables the Calendar window.</td>
</tr>
<tr>
<td>Date/Time Format Builder button</td>
<td>For details, see Editing Date and Time Functions.</td>
</tr>
<tr>

</table>

**Data Editor Filter**

The Data Editor Filter displays the columns of a target table and the corresponding SELECT SQL Statement. You can select columns from the filter for selective data editing.
Notes on XML Types and Unicode Display in the Data Editor

When working with data in the Data editor, keep the following in mind:

- XML data types are supported for IBM DB2 for Windows, Unix, and Linux, Microsoft SQL Server, and Oracle. In the Data editor, XML data types are displayed and entered as LOB content.
- Support for display of Unicode characters is provided as follows:
  - IBM DB2 for Windows, Unix, and Linux: `character`, `clob`, `varchar`, and `longvarchar` types
  - SQL Server: `nchar`, `nvarchar`, `ntext`, and `nvarchar(max)` types.
  - Oracle 9i, and 10g: `NCHAR`, `NVARCHAR2` and `NCLOB` for non-Unicode UTF8 Character Set Instances and `NCHAR`, `NVARCHAR2`, `CHAR`, `VARCHAR2`, `LONG`, `NCLOB` and `CLOB` for Unicode UTF8 Character Set Instances
  - Sybase ASE 12.5 and 15.2: `UNICHAR`, `UNIVARCHAR` and `UNITEXT` for non-Unicode UTF8 Character Set Instances and `UNICHAR`, `UNIVARCHAR`, `UNITEXT`, `NCHAR`, `NVARCHAR`, `CHAR`, `VARCHAR` and `TEXT` for Unicode UTF8 Character Set Instances

Topics

- [Using Data Editor](#)
Using Data Editor

Data Editor lets you edit data in your tables with any editable datatype without leaving the parent application. Data Editor lets you use your new data immediately.

**Caution:** Data Editor is a real-time editor. Changes in your data using Data Editor are permanent.

The table below describes the functions and options of the Data Editor:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Live</td>
<td>Edits data one row at a time. You must execute when you leave the row.</td>
</tr>
<tr>
<td>Batch</td>
<td>Edits data in multiple rows before executing.</td>
</tr>
</tbody>
</table>

**Note:** You can also use the Data Editor to edit date and time functions in a table. For details, see [Editing Date and Time Functions](#).

**Note:** If you make an incorrect edit in a cell, Data Editor displays the error on the Error Tab of the ISQL Editor. Data Editor does not incorporate this error(s) in data into the table. Data Editor saves any changes in data prior to the error message.

**Caution:** Data Editor is a real-time editor. Changes in your data using Data Editor are permanent.

Editing Date and Time Functions

The Data Editor lets you edit date and time functions in a table. Data Editor uses a calendar tool to guarantee accurate input for date and time data. You can also change the display of date and time using the Date/Time Format Builder.

For more information, see:

- [Editing Date and Time Functions](#)

Date/time Format Builder

The Date/Time Format Builder lets you customize your date/time display. The Data Editor uses this format to display your dates and times. You control how the Data Editor displays the dates and time by using predefined formats, or by customizing a format to fit your needs.

The Data Editor uses the default date/time format of your Operating System. If you do not make any global changes, the Date/Time Format Builder displays dates and times using the default formats of your operating system. If you make changes to dates and times in the Data Editor, the changes are committed in the format used by the database.

**Note:** The changes you make using the Date/Time Format Builder do not affect the way your database stores dates and times.
**Editing the Date/time Display**

You can edit the date/time display on a global, table, or column level. The table below describes the different ways you can edit your date/time format display:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global</td>
<td>Lets you make global changes to the Data Editor date display from the Data Editor Tab of the Options Editor. For details, see <a href="#">Editing date/time globally</a>.</td>
<td>Options Editor</td>
</tr>
<tr>
<td>Grid</td>
<td>Lets you make changes to the date display of the entire Data Editor grid for that session only. For details, see <a href="#">Editing grid date/time</a>.</td>
<td>Data Editor grid</td>
</tr>
<tr>
<td>Column</td>
<td>Lets you make changes to the date display of a single column in the Data Editor for that session only. For details, see <a href="#">Editing column date/time</a>.</td>
<td>Data Editor column</td>
</tr>
</tbody>
</table>

**Note:** Date/Time formats changed on a table or column level are valid for that session only.

### Editing date/time globally

You can use the Options Editor to make global changes to your date/time display in the Data editor. When you change the date/time format, using the Options Editor, the Data Editor displays all dates and times in the global manner. To change the date/time display for a particular session, see [Editing grid date/time](#) or [Editing column date/time](#).

To edit the date and time globally, do the following:

1. On the **File** menu, click **Options**.
   
The Options Editor opens.

2. On the Options Editor, click the Data Editor Tab.

3. On the Data Editor Tab, click ...

   The Date/Time Format Builder dialog box opens.

4. On the Date/Time Format Builder dialog box, click the Date/Time Format list, and then click the target predefined date/time format.

5. To customize the date/time format to your specifications, click **Customize**.

   The Date/Time Format Builder dialog box opens.

6. On the Date/Time Format Builder dialog box, select the appropriate Date/Time Format Options:
### Using Data Editor

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date/Time Format</td>
<td>Displays the predefined Date/Time format.</td>
</tr>
<tr>
<td>Day Format</td>
<td>Lets you choose the day display.</td>
</tr>
<tr>
<td>Separator</td>
<td>Lets you choose the display separator between the day, month, and year.</td>
</tr>
<tr>
<td>Month Format</td>
<td>Lets you choose the month display.</td>
</tr>
<tr>
<td>Year Format</td>
<td>Lets you choose the year display.</td>
</tr>
<tr>
<td>Date Order</td>
<td>Lets you choose the date order display.</td>
</tr>
<tr>
<td>Hour Format</td>
<td>Lets you choose the hour display.</td>
</tr>
<tr>
<td>Minute</td>
<td>Lets you choose the minute display.</td>
</tr>
<tr>
<td>Sec Format</td>
<td>Lets you choose the second display.</td>
</tr>
<tr>
<td>AM/PM</td>
<td>Lets you choose the AM/PM display.</td>
</tr>
<tr>
<td>Date/Time Order</td>
<td>Lets you choose the date/time order display.</td>
</tr>
<tr>
<td>Format Display</td>
<td>Displays the current format.</td>
</tr>
<tr>
<td>Sample</td>
<td>Displays a sample of the current format.</td>
</tr>
</tbody>
</table>

7. When you have finished selecting the Date/Time format options, click OK.
   The date/time format changes are accepted the Date/Time Format Builder dialog box closes.

8. On the Options Editor, select the appropriate Default Date/Time Format options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Calendar Control as default</td>
<td>If selected, the <strong>Calendar Control</strong> window is used. For details, see <strong>Editing Date and Time Functions</strong>.</td>
</tr>
<tr>
<td>Two-digit year system setting warning</td>
<td>If selected, a warning is sent when you use a two-digit year system setting.</td>
</tr>
</tbody>
</table>

9. Click OK.
   The Default Date/Time Format changes are accepted the Options Editor closes.

**Note:** To use a different format for a particular session, change the date/time at the session level.
Editing grid date/time

You can change the date/time display for a particular session when working in the Data Editor.

The Data Editor does not maintain the format changes once you close your session. To make this display permanent, use the Editing Global Date/Time Format. For details, see Editing date/time globally.

To edit the grid date and time, do the following:

1. On the Datasource Navigator/Explorer, select the target table.
2. Right-click the table, and then click Edit Data.

The Data Editor opens.

3. On the Data Editor tool bar, click Date/Time Format Builder.

The Date/Time Format Builder opens.

4. On the Date/Time Format Builder, click the Date/Time Format list, and then click the target predefined date/time format.
5. To customize the date/time format to your specifications, click Customize.

The Date/Time Format Builder dialog box opens.

6. On the Date/Time Format Builder dialog box, select the appropriate Date/Time Format Options:
Using Data Editor

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date/Time Format</td>
<td>Displays the predefined Date/Time format.</td>
</tr>
<tr>
<td>Day Format</td>
<td>Lets you choose the day display.</td>
</tr>
<tr>
<td>Separator</td>
<td>Lets you choose the display separator between the day, month, and year.</td>
</tr>
<tr>
<td>Month Format</td>
<td>Lets you choose the month display.</td>
</tr>
<tr>
<td>Year Format</td>
<td>Lets you choose the year display.</td>
</tr>
<tr>
<td>Date Order</td>
<td>Lets you choose the date order display.</td>
</tr>
<tr>
<td>Hour Format</td>
<td>Lets you choose the hour display.</td>
</tr>
<tr>
<td>Minute</td>
<td>Lets you choose the minute display.</td>
</tr>
<tr>
<td>Sec Format</td>
<td>Lets you choose the second display.</td>
</tr>
<tr>
<td>AM/PM</td>
<td>Lets you choose the AM/PM display.</td>
</tr>
<tr>
<td>Date/Time Order</td>
<td>Lets you choose the date/time order display.</td>
</tr>
<tr>
<td>Format Display</td>
<td>Displays the current format.</td>
</tr>
<tr>
<td>Sample</td>
<td>Displays a sample of the current format.</td>
</tr>
</tbody>
</table>

7. When you have finished selecting the Date/Time format options, click OK.

The date/time format changes are accepted and the Date/Time Format Builder dialog box closes.

- To undo changes, on the Data Editor tool bar, click Undo Change.
- To redo changes, on the Data Editor tool bar, click Redo Change.

**Note:** Date/Time formats changed on a table level are valid for that session only.

**Editing column date/time**

You can change the date/time display for a particular column when working in the Data Editor.

The Data Editor does not maintain the format changes once you close your session. To change the format for the entire grid, see Editing Grid Date/Time Format. For details, see Editing grid date/time.

To make this display permanent, Editing Global Date/Time Format. For details, see Editing date/time globally.

To edit the column date and time, do the following:

1. On the Datasource Navigator/Explorer, select the target table.
2. Right-click the table, and click Edit Data.

The Data Editor opens.

3. On the Data Editor, click the column header to select the column.

4. Right-click the column and click Format.

The Date/Time Format Builder opens.

5. On the Date/Time Format Builder dialog box, click the Date/Time Format list, and then click the target predefined date/time format.

6. To customize the date/time format to your specifications, click Customize.

The Date/Time Format Builder dialog box opens.

7. On the Date/Time Format Builder dialog box, select the appropriate Date/Time Format Options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date/Time Format</td>
<td>Displays the predefined Date/Time format.</td>
</tr>
<tr>
<td>Day Format</td>
<td>Lets you choose the day display.</td>
</tr>
<tr>
<td>Separator</td>
<td>Lets you choose the display separator between the day, month, and year.</td>
</tr>
<tr>
<td>Month Format</td>
<td>Lets you choose the month display.</td>
</tr>
<tr>
<td>Year Format</td>
<td>Lets you choose the year display.</td>
</tr>
<tr>
<td>Date Order</td>
<td>Lets you choose the date order display.</td>
</tr>
<tr>
<td>Hour Format</td>
<td>Lets you choose the hour display.</td>
</tr>
<tr>
<td>Minute</td>
<td>Lets you choose the minute display.</td>
</tr>
<tr>
<td>Sec Format</td>
<td>Lets you choose the second display.</td>
</tr>
<tr>
<td>AM/PM</td>
<td>Lets you choose the AM/PM display.</td>
</tr>
<tr>
<td>Date/Time Order</td>
<td>Lets you choose the date/time order display.</td>
</tr>
<tr>
<td>Format Display</td>
<td>Displays the current format.</td>
</tr>
<tr>
<td>Sample</td>
<td>Displays a sample of the current format.</td>
</tr>
</tbody>
</table>

8. When you have finished selecting the Date/Time format options, click OK.

The date/time format changes are accepted and the Date/Time Format Builder dialog box closes.

- To undo changes, on the Data Editor tool bar, click Undo Format.
- To redo changes, on the Data Editor tool bar, click Redo Format.
**Using Data Editor**

**Note:** Date/Time formats changed on a column level are valid for that session only.

**Default Value Handling**

When adding new records, when the transaction committing a row occurs, if no value has been entered for a column defined as having a default value, the default value is used for that column and validation is not required. The default value is not visible in the Data Editor grid until you commit the record and use the Reload Data button to refresh the grid.

In the case of tables with all columns defined as having default values, for example, you can add multiple records by repeatedly clicking the Insert New Record and Save Current Row buttons.

**Page setup**

The table below describes the options and functionality on the Page Setup dialog box:

<table>
<thead>
<tr>
<th>Option</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Margins</td>
<td>Lets you select the size of the left, right, top, and bottom margins.</td>
</tr>
<tr>
<td>Titles and Gridlines</td>
<td>Lets you select options.</td>
</tr>
<tr>
<td>Preview</td>
<td>Displays how the table will appear when printed.</td>
</tr>
<tr>
<td>Page Order</td>
<td>Lets you specify when to print columns and rows.</td>
</tr>
<tr>
<td>Center on Page</td>
<td>Lets you select how table floats on the page.</td>
</tr>
</tbody>
</table>
Add-on tools

The following are the available, license-specific tools.

- **Embarcadero SQL Debugger** - Provides detailed information about using the Embarcadero SQL Debugger. It includes a step-by-step walk through to familiarize you with the features of the Embarcadero SQL Debugger.

- **PL/SQL Profiler** - Provides detailed information about using the DBArtisan PL/SQL Profiler. Includes a step-by-step walk through to familiarize you with the features of the PL/SQL Profiler.

- **Capacity Analyst** - Collects critical database storage, object, and performance metrics at scheduled intervals and provides visual analysis and reporting mechanisms that allow for historical trend analysis and forecasting.

- **Performance Analyst** - Provides a robust client-side monitoring product that presents a complete picture of a database’s performance.

- **Space Analyst** - Provides sophisticated diagnostic capabilities to help you effectively locate and troubleshoot bottlenecks and performance inefficiencies that result from the challenges of space management.

Topics

- **Licensing Your Product**
Embarcadero SQL Debugger

The Embarcadero SQL Debugger lets you locate and fix bugs in the following elements:

- Procedures (IBM DB2 for Linux, Unix, and Windows, Microsoft SQL Server, Oracle, Sybase ASE)
- Functions (Oracle)
- Triggers (IBM DB2 for Linux, Unix, and Windows, Microsoft SQL Server, Oracle, Sybase ASE)

**Note:** The SQL Debugger lets you debug triggers by debugging the procedures that call them.

**Note:** For Oracle, you cannot debug packages, but you can debug the functions and procedures within packages.

**Note:** For Oracle, you cannot debug any objects contained in the Exclusion List. For more information, see [Editing the Exclusion List](#).

The table below describes the sections of this chapter:

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Debugger Modules and DBMS Support</td>
<td>Describes the specific SQL Debugger modules and DBMS versions supported.</td>
</tr>
<tr>
<td>Embarcadero SQL Debugger Features</td>
<td>Provides an overview of SQL Debugger functionality.</td>
</tr>
<tr>
<td>Setting up the Embarcadero SQL Debugger</td>
<td>Provides details on requirements and setup tasks for each supported DBMS.</td>
</tr>
<tr>
<td>Embarcadero SQL Debugger Interface</td>
<td>Describes the Embarcadero SQL Debugger graphical interface that includes an editor window and four debug view windows.</td>
</tr>
<tr>
<td>Embarcadero SQL Debugger Functionality</td>
<td>This section describes the functionality on the SQL Debugger.</td>
</tr>
<tr>
<td>Using the Embarcadero SQL Debugger</td>
<td>This section describes how to run a debug session.</td>
</tr>
<tr>
<td>Tutorial Sessions</td>
<td>Provides walkthrough sessions for new users.</td>
</tr>
</tbody>
</table>
SQL Debugger Modules and DBMS Support

There are four Embarcadero SQL Debugger modules, each corresponding to a supported DBMS. Modules and DBMS support are as follows:

- **Embarcadero SQL Debugger for IBM DB2 for Linux, Unix, and Windows**: supports all versions supported by DBArtisan
- **Embarcadero SQL Debugger for Microsoft**: supports all versions supported by DBArtisan
- **Embarcadero SQL Debugger for Oracle**: supports all versions supported by DBArtisan
- **Embarcadero SQL Debugger for Sybase ASE**: supports all versions supported by DBArtisan

Each SQL Debugger version is an optional and separate add-on module.
Embarcadero SQL Debugger Features

The Embarcadero SQL Debugger lets you identify problems within your code. The Embarcadero SQL Debugger lets you:

- Interactively step through the flow of script execution.
- Examine the value of variables.
- Solve logical problems with your script design.

**Note:** The Debugger is available on the main menu, the Procedures window, the DDL Editor and ISQL windows.

The Embarcadero SQL Debugger offers fundamental debugging features and options to fine tune debugging. The table below describes these features:

<table>
<thead>
<tr>
<th>Debugging Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step Into</strong></td>
<td>Lets you execute each instruction step-by-step and step inside a stored object.</td>
</tr>
<tr>
<td><strong>Step Out</strong></td>
<td>Lets you stop stepping through the current object and execute the remainder of the script. This option is only active when the pointer indicates a child dependent instruction.</td>
</tr>
<tr>
<td><strong>Step Over</strong></td>
<td>Lets you execute the current instruction without stepping into any child dependents.</td>
</tr>
<tr>
<td><strong>Insert or Remove Breakpoint</strong></td>
<td>Lets you specify positions in a program where the debugger stops execution.</td>
</tr>
</tbody>
</table>

To set specific Debugger values on the Options Editor, see [Embarcadero SQL Debugger Options](#).
Setting up the Embarcadero SQL Debugger

The following topics describe requirements and tasks for those DBMS that have setup requirements:

- Embarcadero SQL Debugger for Linux, Unix, and Windows Setup
- The Embarcadero SQL Debugger for Microsoft Setup
- Embarcadero SQL Debugger for Oracle Setup

In addition, you should set your debugger preferences at this time. For details, see Embarcadero SQL Debugger Options.
Embarcadero SQL Debugger for Linux, Unix, and Windows Setup

Embarcadero SQL Debugger for IBM DB2 for Linux, Unix, and Windows requires proper configuration of the server and client.

For more information, see:

- Prerequisites for Adding and Compiling Stored Procedures
- Configuring the IBM DB2 for Linux, Unix, and Windows Server for Procedures
- Prerequisites for Debugging Procedures

Prerequisites for Adding and Compiling Stored Procedures

The Embarcadero SQL Debugger for IBM DB2 for Linux, Unix, and Windows requires the following products and components.

Client

- IBM DB2 for Linux, Unix, and Windows
- DB2 Application Development Client
- DB2 Administration Client
- Communications Protocols
- Stored Procedure Builder
- Applications Development Interfaces
- System Bind Files
- DB2 Connect Server Support
- Documentation
- Base DB2 for Windows/Unix Support
- Administration and Configuration Tools

Server

- IBM DB2 for Linux, Unix, and Windows
- DB2 Enterprise Edition
- Communications Protocols
- Stored Procedure Builder
Embarcadero SQL Debugger for Linux, Unix, and Windows Setup

- Applications Development Interfaces
- System Bind Files
- DB2 Connect Server Support
- Documentation
- Base DB2 for Windows/Unix Support
- Administration and Configuration Tools
- Microsoft Visual Studio, Visual C++

**Note:** The server must have a local directory structure and file `C:\program files\sqllib\function\routine\sr_cpath.bat`. This file is installed with IBM DB2 and includes the C compiler options needed to compile the procedure on the server. If it is not found, install the IBM DB2 Administration and Configuration Tools option on the server.

### Configuring the IBM DB2 for Linux, Unix, and Windows Server for Procedures

You can create procedures on the targeted server.

To create or run any procedure, set up the configuration environment and enable the C compiler options on the server.

To configure your server, do the following:

1. Open a DB2 Command Window, and then type:

   ```
   DB2set DB2_SQLROUTINE_COMPILER_PATH="C:\program files\sqllib\function\routine\sr_cpath.bat"
   ```

   DB2 sets the `DB2_SQLROUTINE_COMPILER_PATH` DB2 registry variable to call the required initialization script for the C compiler on the server.

To enable the C compiler options on your server:

1. Open the file `C:\program files\sqllib\function\routine\sr_cpath.bat`.

2. Remove the REM (remarks) prefix on the lines that match the version of Visual Studio that is installed on the server. VCV6 = version 6.0 and VCV5 = version 5.0.

**Note:** Only remove the REM prefix on the lines that apply to your installation of Visual Studio.

3. Restart the DB2 services on the server.

### Prerequisites for Debugging Procedures

To enable debugging on the server, do the following:

1. Open a DB2 Command window and type:
Db2set  DB2ROUTINE_DEBUG=ON

**Note:** Availability of this feature depends on your licensing.

**Topics**

- [Licensing Your Product](#)
The Embarcadero SQL Debugger for Microsoft Setup

Embarcadero SQL Debugger for Microsoft requires proper configuration of Server Requirements and Client Requirements.

Important Note about Microsoft SQL Server 2000 Service Pack 4 (SP4)

When running Windows XP SP2, SQL Server 2000 SP4 is required on both the client and the server. To verify this is the case start MS Query Analyzer and press Help > About. The Version SQL should be 8.00.2039.

Important Notes about Microsoft SQL Server 2000 Service Pack 3 (SP3)

By default, after you install Microsoft SQL Server 2000 Service Pack 3 (SP3), you cannot use the T-SQL Debugger.

You may receive the following error message if you try to use the T-SQL Debugger:

“Server: Msg 514, Level 16, State 1, Procedure sp_sdidebug, Line 1 [Microsoft][ODBC SQL Server Driver][SQL Server]Unable to communicate with debugger on [SQL Server Name] (Error = 0x80070005). Debugging disabled for connection 53.”

Microsoft has disabled T-SQL Debugger for Application using earlier T-SQL Debugger clients for security reasons. To enable T-SQL Debugger for these Applications, a member of the sysadmins server role, such as sa must explicitly enable debugging by running the following code:

Exec sp_sdidebug 'legacy_on'

Note: You must repeat this procedure whenever you restart the server.

Server Requirements

Embarcadero SQL Debugger for Microsoft requires:

- Windows 2005
- Windows 2000
- Microsoft SQL Server version 7.0 or later

Setting Up the Server

There are three parts to setting up the server:

- Installing the Microsoft SQL Debugger Interface Subcomponent
- Configuring the Service
- Configuring DCOM on the Server
Enabling SQL Debugger for Microsoft on SQL Server SP3

SQL Debugging is disabled by default in SQL Server SP3 and greater. Please refer to Microsoft Support for information regarding enabling the SQL Debugger for Microsoft on SQL Server SP3.

Installing the Microsoft SQL Debugger Interface Subcomponent

The Microsoft server must have the Development Tools, Debugger Interface subcomponent of Microsoft SQL Server. To determine if the Debugger Interface subcomponent is installed, locate the following files in the \Program Files\Common Files\Microsoft Shared\SQL Debugging directory:

- SQLDBREG.exe
- SQLDBG.dll

If these files are not in the \Program Files\Common Files\Microsoft Shared\SQL Debugging directory, install them before running the Embarcadero SQL Debugger for Microsoft.

To install the Debugger Interface subcomponent on the server after the initial installation:

OR

Start Microsoft SQL Server Setup.

2. Select Custom Install.

Microsoft SQL Server opens the Select Components dialog.

3. In the Components box, select the Development Tools check box.

4. In the Sub-components box, select the Debugger Interface check box.

5. Click Next.

Microsoft SQL Server proceeds through the Microsoft SQL Server wizard to install the components.

Configuring the Service

To configure the service, see the instructions for your server operating system.

Windows 2000

1. On the Windows taskbar, click the Start button, click Settings, and then click Control Panel.
2. Double-click **Administrative Tools**, and then click **Services**.

Windows opens the Services explorer.

3. In the right pane of the Services explorer, right click **MSSQLServer**, and then click **Properties**.

Windows opens the **Net Logon Properties** dialog.

4. Click the **Logon** tab.

5. Select the **This Account** option button.

6. In the This Account box, type (or browse to locate) the logon user account (including domain name, if necessary) of the person who will be using the Embarcadero SQL Debugger for Microsoft.

**Note:** This person needs admin permissions on the server.

7. In the Password and Confirm Password boxes, type the password.

8. Click **Apply**.

9. Click the **General** tab.

10. Click **Start**.

Windows starts the server and applies the changes.

**Important Note about Microsoft SQL Server 2000 Service Pack 4 (SP4)**

When running Windows XP SP2, SQL Server 2000 SP4 is required on both the client and the server. When running Windows XP SP2, SQL Server 2000 SP4 is required on both the client and the server. To verify this is the case start MS Query Analyzer and press Help > About. The Version SQL should be 8.00.2039.

**Important Notes about Microsoft SQL Server 2000 Service Pack 3 (SP3)**

By default, after you install Microsoft SQL Server 2000 Service Pack 3 (SP3), you cannot use the T-SQL Debugger.

You may receive the following error message if you try to use the T-SQL Debugger:

“Server: Msg 514, Level 16, State 1, Procedure sp_sdidebug, Line 1
[Microsoft][ODBC SQL Server Driver][SQL Server]Unable to communicate with debugger on [SQL Server Name] (Error = 0x80070005). Debugging disabled for connection 53.”

Microsoft has disabled T-SQL Debugger for Application using earlier T-SQL Debugger clients for security reasons. To enable T-SQL Debugger for these Applications, a member of the sysadmins server role, such as sa must explicitly enable debugging by running the following code:

Exec sp_sdidebug 'legacy_on'
Note: You must repeat this procedure whenever you restart the server.

Configuring DCOM on the Server

To configure DCOM on the server, do the following:

1. After the server restarts, on the Windows taskbar, click the Start button, and then click Run.
2. In the Open box, type dcomcnfg.exe.
3. Click OK.

Windows opens the Distributed COM Configuration Properties dialog.

4. Click the Default Security tab.
5. In the Default Access Permissions box, click Edit Default.

Windows opens the Registry Value Permissions dialog.

6. Click Add.

Windows opens the Add Users and Groups dialog.

7. In the Names box, select SYSTEM, and then click Add.
8. Click the Type of Access list, and then click Allow Access.
9. To let any user use the Embarcadero SQL Debugger for Microsoft, grant them remote access on the server. To grant remote access, configure their DCOM permissions on the server. In the Names box, click the target users, and then click Add.

Note: You can add individual users or groups.

10. Click the Type of Access list, and then click Allow Access.
11. Click OK.
12. Restart the server to apply the changes.

Client Requirements

There are three categories of client requirements for the Embarcadero SQL Debugger for Microsoft:

- Operating System
- Client Connectivity
- Installing the Microsoft SQL Debugger Interface Subcomponent
Operating System

The client must be running one of the following operating systems:

- Microsoft Windows 95
- Microsoft Windows 98
- Microsoft Windows XP

Client Connectivity

When running the Debugger on SQL Server Clients

Before you proceed, verify that the file ssdebugps.dll is registered on the client machine. This file is REQUIRED for debugging and Microsoft only installs it on the server machine and not as a part of a client-only install.

Next you must configure DCOM by following these steps:

1. At a command prompt, type dcomcnfg, and then press ENTER.

Component Services opens.

2. In Component Services, expand Component Services, expand Computers, and then expand My Computer.

3. On the toolbar, click the Configure My Computer button.

The My Computer dialog appears.

4. In the My Computer dialog, click the COM Security tab.

The Access Permission dialog appears.

6. Under Group or user names, click ANONYMOUS LOGON.

7. Under Permissions for ANONYMOUS LOGON, select the Remote Access check box, and then click OK.

Finally, you need to go to the Default Properties tab of the MyComputer dialog.

1. Select None in the Default Authentication Level dropdown menu.

2. Select Impersonate in the Default Impersonation Level dropdown menu.

For more detailed information, you can refer to Microsoft’s Help: http://support.microsoft.com/default.aspx?kbid=833977#XSLTH4134121124120121120120

When running Windows XP SP2, SQL Server 2000 SP4 is required on both the client and the server.
For Microsoft SQL the client must have the Client Connectivity component of Microsoft SQL Server.

**For Microsoft SQL Server**

The client must have the Development Tools, Debugger Interface subcomponent of Microsoft SQL Server. To determine if the Debugger Interface subcomponent is installed, locate the following files in the `\Program Files\Common Files\Microsoft Shared\SQL Debugging` directory:

- SQLDBREG.exe
- SQLDBG.dll

If these files are not in the `\Program Files\Common Files\Microsoft Shared\SQL Debugging` directory, install them before running the Embarcadero SQL Debugger for Microsoft.

**Installing the Microsoft SQL Debugger Interface on the Client**

To install the Debugger Interface subcomponent on the client, do the following:

1. Start the Microsoft SQL Server Setup program.
2. Select Custom Install.

Microsoft SQL Server opens the Select Components dialog.

3. In the Components box, select the Development Tools check box.
4. In the Sub-Components box, select the Debugger Interface check box.
5. Click **Next**.

Microsoft SQL Server proceeds through the Microsoft SQL Server Wizard to install the components.
Embarcadero SQL Debugger for Oracle Setup

The only task required in setting up the Embarcadero SQL Debugger for Oracle is Editing the Exclusion List.

Editing the Exclusion List

Upon installation, an Exclusion List is set up on your computer which includes packages that the application cannot debug. The Exclusion List is located in the main product directory. You can add or remove packages from this file by editing the Exclusion List.

To Edit the Exclusion List, do the following:

1. Open the Exclusion List, deborcex.etd, in a text editor, such as Microsoft Notepad or WordPad.
2. To add a package, enter the name of the package at the end of the list. Use the following format: OWNER.OBJECT_NAME.
   Note: Press ENTER after each item on the list.
3. To remove a package from the Exclusion List, delete the package from the list.
   Note: Embarcadero SQL Debugger for Oracle does not debug a package function or package procedure listed on the Exclusion List.
4. Save the changes to deborcex.etd.
Embarcadero SQL Debugger Options

You can specify debugger options from the Debug tab of the Options editor.

Topics

- Debug Options

Embarcadero SQL Debugger Interface

The Embarcadero SQL Debugger includes an editor window and four debug view windows. When you open a debug session, the code for the object is extracted into a DDL Editor and opens four debug view windows at the bottom of the screen. The four debug view windows are optional, dockable windows designed to let you debug your script.

Tip: All Embarcadero debuggers display Performance Metrics that let you measure the execution time of each statement in the debug session.

The Embarcadero SQL Debugger includes five windows:

- DDL Editor Window
- Watch Window
- Variables Window
- Call Stack Window
- Dependency Tree Window

Working with SQL Debugger Windows

You can resize, move, dock and float the following windows:

- Watch Window
- Variables Window
- Call Stack Window
- Dependency Tree Window

The process to do it is:

1. To resize the target window, click its frame and drag it.
2. To move and dock the target window, click its grab bar and drag it.
3. To float the target window, press Shift, then click its grab bar and drag it.
DDL Editor Window

The DDL Editor displays your code in read-only format. When you start debugging, the Embarcadero SQL Debugger extracts your code into a DDL Editor. The DDL Editor uses the default syntax coloring.

Note: For Oracle, LOB datatypes and REF CURSOR variables are displayed in the Results tab.

Topics

- [Embarcadero SQL Debugger Interface](#)
Watch Window

The Watch window displays the watch variables for the database object you are debugging. The Watch window also lets you specify variables you want to evaluate or modify while debugging your program.

For example, to check what happens when a variable (x) has a value of 100, you can double-click the variable in the DDL Editor, drag it into the Watch Window, and change the value to 100. When you execute the script, the Debugger uses the value $x = 100$. This window is only visible when the SQL Debugger is active.

**Note:** Until you step at least once into a script, variables are not defined. Therefore, step at least once before dragging or typing a local variable in the Watch Window.

**Note:** You can type a fully qualified record variable into the Watch window.

**Note:** When you exit a debug session and reenter it, the Embarcadero SQL Debugger retains any watch variables or breakpoints you have set.

Opening and Closing the Watch Window

To open and close the Watch Window, do the following:

1. On the **Debug** menu, on the **Debug Views** sub-menu, select or clear **Watch**.

OR

Press ALT+3.

Setting a Watch Variable

To set a Watch Variable, do the following:

1. In the DDL Editor, double-click the target variable and drag it to the Watch window.

**Note:** Microsoft SQL Server requires that local variables begin with @. Drag the @ to the Watch Window.

2. In the Watch window, change the value of the variable.

3. On the DDL Editor, click **Debug** or **Go**.

The Embarcadero SQL Debugger executes the script using the new variable.

Removing a Watch Variable

To remove a Watch variable, do the following:

1. In the Watch window, click the target variable and press DELETE.
Variables Window

The Variables window displays the local variables and their current values during script execution.

**Note:** You cannot edit the variables in the Variables window.

If the DDL Editor displays an external database object, and that object is a dependent of the object you are debugging, then the Variables Window automatically refreshes and displays the variables for that particular object. The Variables Window is only visible when the Debugger is active.

The Embarcadero SQL Debugger also lets you monitor your variables while debugging.

**Opening and Closing the Variables Window**

To open and close the Variables Window, do the following:

1. On the Debug menu, on the Debug Views sub-menu, select or clear Variable.

OR

Press ALT+4.

**Monitoring Variables**

To monitor the values of your variables while debugging, do the following:

1. In the SQL Editor, hold the pointer over the target variable.

A ScreenTip displaying the current value of that variable displays.

**Topics**

- Embarcadero SQL Debugger Interface
Call Stack Window

The Call Stack window displays the stack of currently active calls. The Call Stack Window is only visible when the Debugger is active.

Opening and Closing the Call Stack Window

To open and close the Call Stack Window, do the following:

1. On the Debug menu, on the Debug Views sub-menu, select or clear Call Stack.

OR

Press ALT+5.

Using the Call Stack Window

To display a line of code that references the call in the DDL Editor, do the following:

1. In the Call Stack window, double-click the target line.

In the DDL Editor, a green arrow indicates the line of the referenced call.

Topics

- Embarcadero SQL Debugger Interface
Dependency Tree Window

The Dependency Tree window displays any external database objects the script accesses. These database objects are displayed in a hierarchical tree, with the child objects as database objects accessed by the parent objects. You can use this window to display the code for a dependent database object in the DDL Editor window. This window is only visible when the Debugger is active.

Opening and Closing the Dependency Tree Window

To open and close the Dependency Tree Window, do the following:

1. On the Debug menu, on the Debug Views sub-menu, select or clear Dependencies.

OR

Press ALT+6.

Displaying Dependencies

To display the code for a dependent database object in the DDL Editor window, do the following:

1. In the Dependency Tree window, double-click the target object.

The SQL of the target object is displayed in the DDL Editor window.

Topics

- Embarcadero SQL Debugger Interface
Embarcadero SQL Debugger Functionality

The Embarcadero SQL Debugger offers the following functionality:

- **Input Parameters**
- **Step Into**
- **Step Out**
- **Step Over**
- **Run To Cursor**
- **Insert or Remove Breakpoint**
- **Toggle Breakpoint**
- **Go**
- **Stop**
- **Restart**
- **Break**
- **Close**

You must be running a debugging session to use these functions.

**Topics**

- **Opening a Debugging Session**.
Input Parameters

Input parameters are set when you first create an object. If the object you want to debug requires input parameters, a dialog box prompts you for the input parameters when you open a debugging session.

The **Procedure Execution** dialog also lets you:

- Save input parameters as *.prm files to preserve specific input parameter configurations.
- Open *.prm files to save the effort of reentering specific input parameters.
- Reset parameters to their default setting.

The following table describes the options available in this dialog box:

<table>
<thead>
<tr>
<th>Dialog box component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner drop-down list</td>
<td>Displays the current procedure’s owner</td>
</tr>
<tr>
<td>Procedure drop-down list</td>
<td>Displays the name of the current procedure.</td>
</tr>
<tr>
<td>Parameter window</td>
<td>Specify the required input parameters in this window. If input parameters are not required for the execution of the target procedure, a message appears in this window, stating that the procedure &quot;has no input parameters. Press execute to run it.&quot;</td>
</tr>
<tr>
<td>Open button</td>
<td>Click to open an <strong>Open</strong> dialog, from which you can open an existing *.prm file. The saved parameters immediately populate the dialog box upon opening.</td>
</tr>
<tr>
<td>Save button</td>
<td>Click to save the values of your input parameters as a *.prm file. You can reopen a saved *.prm file from this dialog box at any time.</td>
</tr>
<tr>
<td>Reset button</td>
<td>Click to reset the parameters in the Parameter window to their default values.</td>
</tr>
<tr>
<td>Execute or Continue button</td>
<td>Click to execute the procedure once you have entered values for all required parameters in the Parameter window.</td>
</tr>
</tbody>
</table>

**Note:** You cannot debug a script that requires input parameters until you provide input parameters.

**Topics**

- [Embarcadero SQL Debugger Functionality](#)
Step Into

Step Into lets you execute the current instruction. If the current instruction makes a call to a stored SQL object, the Embarcadero SQL Debugger steps inside the nested child object.

To use the Step Into facility, do the following:

1. On the Debug menu, select Step Into.

OR

Press F11.

The Embarcadero SQL Debugger moves the arrow to execute the current instruction.

Topics

- Embarcadero SQL Debugger Functionality
Step Out

Step Out lets you execute the remainder of the dependent child object and resumes line-by-line, step-debugging in the parent object.

**Note:** Step Out is only active when the pointer indicates a child dependent instruction.

To use the Step Out facility, do the following:

1. On the **Debug** menu, select **Step Out**.

OR

Press SHIFT+F11.

The Embarcadero SQL Debugger stops stepping through the current object and executes the remainder of the script.

**Topics**

- [Embarcadero SQL Debugger Functionality](#)
Step Over

Step Over lets you execute the current instruction without stepping into a nested child object if the instruction makes a call to a dependent object.

To use the Step Over, do the following:

1. On the Debug menu, select Step Over.

OR

Press F10.

The Embarcadero SQL Debugger executes the current instruction.

Topics

- Embarcadero SQL Debugger Functionality

Run To Cursor

Run to Cursor lets you execute all instructions between the yellow arrow and the cursor.

To use the Run to Cursor facility, do the following:

1. Scroll down from the yellow arrow to the target line.
2. Click the target line.

Embarcadero SQL Debugger places the cursor on the target line.

3. On the Debug menu, select Run to Cursor.

OR

Press CTRL+F10.

The Embarcadero SQL Debugger executes all instructions between the pointer and the cursor.

Topics

- Embarcadero SQL Debugger Functionality
**Insert or Remove Breakpoint**

A breakpoint is a position in a program where a debugger stops execution. When you start debugging, Embarcadero SQL Debugger opens the script in a DDL Editor. A yellow arrow pointer indicates which line the Embarcadero SQL Debugger executes next.

The Embarcadero SQL Debugger executes all lines of code between the yellow arrow and the first breakpoint. If no breakpoints are present, Embarcadero SQL Debugger debugs the entire script.

While debugging you can set one or more breakpoints in the currently executing object or in any object in the program call stack. You can Toggle Breakpoints, temporarily disable or enable breakpoints without having to add or remove breakpoints.

The Embarcadero SQL Debugger displays each enabled breakpoint as a red dot in the left margin of the DDL Editor Window, and each disabled breakpoint as a red circle.

Breakpoints are stored so that when you debug the same script on separate occasions, you can reuse the same breakpoints. You can insert a breakpoint on the line where your cursor is located, and you can remove a breakpoint on the line where your cursor is located.

**Note:** Script execution stops at the first breakpoint.

To insert and remove breakpoints, do the following:

1. In the DDL Editor window, click the target line of SQL.
2. On the Debug menu, select Breakpoint.

OR

Press F9.

The Embarcadero SQL Debugger inserts a new breakpoint or removes an existing breakpoint on the target line of code.

**Topics**

- [Embarcadero SQL Debugger Functionality](#)
Toggle Breakpoint

After inserting a breakpoint, Toggle Breakpoint lets you enable or disable that breakpoint. Embarcadero SQL Debugger displays each enabled breakpoint as a red dot in the left margin of the DDL Editor Window, and each disabled breakpoint as a red circle.

You can toggle any breakpoint in the DDL Editor window. When you exit a debugging session and reenter it, the Embarcadero SQL Debugger retains any breakpoints you set.

To use the Toggle Breakpoint facility, do the following:

1. In the DDL Editor window, click the line of the target breakpoint.

OR

Press CTRL+F9.

The Embarcadero SQL Debugger toggles the breakpoint indicated by the pointer.

Topics

- Insert or Remove Breakpoint
Go

Go lets you execute all instructions stopping only when it encounters a breakpoint or when the program is complete.

To use the Go facility, do the following:

1. On the Debug menu, select Go.

OR

Press F5.

The Embarcadero SQL Debugger executes all instructions.

Topics

○ Embarcadero SQL Debugger Functionality

Stop

Stop lets you halt the script execution and terminate the session.

To use the Stop facility, do the following:

1. On the Debug menu, select Stop Debugging.

OR

Press SHIFT+F5.

The Embarcadero SQL Debugger stops the script execution and terminates the session.

Topics

○ Embarcadero SQL Debugger Functionality
Restart

Restart lets you terminate the current debug session and open a new one. When the new session opens, you are prompted for new input parameters.

To use the Restart facility, do the following:

1. On the Debug menu, select Restart.

OR

Press CTRL+SHIFT+F5.

The Embarcadero SQL Debugger restarts the debug session.

Topics

- Embarcadero SQL Debugger Functionality.

Break

Break lets you pause the debug session.

To use the Break facility, do the following:

1. On the Debug menu, select Break.

The Embarcadero SQL Debugger suspends the debug session.

Topics

- Embarcadero SQL Debugger Functionality.

Close

Close lets you close the DDL Editor and the Embarcadero SQL Debugger.

To use the Close facility, do the following:

1. On the DDL Editor toolbar, click Close.

OR

In the upper right corner of the window, click Close.

OR

In the DDL Editor window, right-click, and then click Close.

The Embarcadero SQL Debugger closes the debug session.
Using the Embarcadero SQL Debugger

This section offers a general overview of how to use Embarcadero SQL Debugger’s full range of debugging functionality.

- **Opening a Debugging Session**
- **Debugging an SQL Script with Embarcadero SQL Debugger**

### Opening a Debugging Session

When you start a debugging session, the Embarcadero SQL Debugger interface opens. For details, see [Embarcadero SQL Debugger Interface](#).

If the target script requires input parameters, a dialog box prompts you for the necessary input parameters before displaying the target code in the SQL Editor window. When the target script is displayed in the SQL Editor window, you can begin debugging. For details, see [Debugging an SQL Script with Embarcadero SQL Debugger](#).

**Note:** Embarcadero SQL Debugger for IBM DB2 for Linux, Unix, and Windows, Embarcadero SQL Debugger for Sybase, and Embarcadero SQL Debugger for Microsoft only let you debug the SQL script of procedures or triggers.

To debug an object, do the following:

1. In the Navigator/Explorer, click the object node.

   The objects are displayed.

2. Right-click the target object, and select **Open**.

   The Object Editor opens.

   **OR**

   Right-click the target object and select **Extract**.

   The DDL Editor opens, displaying the code of the target object.

3. On the toolbar, click **Debug**.

   **OR**

   In the DDL Editor window, right-click, and then click **Debug**.

If the script requests input parameters, a dialog box prompts for parameter values. If the script does not require input parameters, the script is displayed in the DDL Editor window for you to begin debugging. For details, see [Debugging an SQL Script with Embarcadero SQL Debugger](#).

**Note:** You cannot use the Embarcadero SQL Debugger until it has fully initialized.
4. In the dialog box, specify the appropriate parameter values, and then click OK or Continue.

The script opens in the DDL Editor window.

Note: If the script requires Sybase ASE or Oracle types (tables, records, or Booleans) as input parameters, the Embarcadero SQL Debugger generates an anonymous block.

Debugging an SQL Script with Embarcadero SQL Debugger

After you open a debugging session and enter any required input parameters, you can begin working with your script in the Embarcadero SQL Debugger.

Debugging an SQL Script

To debug a SQL Script, do the following:

1. On the Debug menu, click one of the SQL Debugger options (Step Into, Step Over, and so forth) or click Go.

Note: You can monitor the progress of your debug session in the Variables window.

2. On the Debug menu, select Breakpoint.

OR

Press F9.

Note: When you set a breakpoint, the Call Stack window shows what was called before the breakpoint.

Note: You can use the Run To Cursor option to test the lines of code between a breakpoint and your cursor (indicated by the yellow arrow in the DDL Editor).

To check your variables:

1. In the DDL Editor, click a variable in your script and drag it to the Watch window.

2. In the Watch window, change the value of the watch variable, and then click Go to run your script and see the results of the new value.

To check a record in stored objects:

1. Drag the record to the Watch window.

2. In the Watch window, change the value of the record, then click Go to run your script and see the results of the new value.

To check the dependencies:

1. In the Dependency Tree window double-click the target dependent object to extract the code into a new DDL Editor.
2. Step through the script while monitoring the Dependency Tree Window.

3. When you finish debugging the script, click Close or Exit.

The T-SQL Debugger DDL Editor closes.

Note: When you exit a debug session and reenter it, the Embarcadero SQL Debugger for MSSQL retains any watch variables or breakpoints you have set.

Tutorial Sessions

The following topics provide walkthrough sessions geared to new users of the Embarcadero SQL Debugger:

- [Debugging a Sample Script with Embarcadero SQL Debugger for Microsoft](#)
- [Debugging a Sample Script with Embarcadero SQL Debugger for Oracle](#)
Debugging a Sample Script with Embarcadero SQL Debugger for Microsoft

This Getting Started section demonstrates basic debugging functionality. You will debug two procedures using the Embarcadero SQL Debugger for Microsoft.

The section topics are designed to familiarize you with basic debugging features and functionality:

- Getting Started with Embarcadero SQL Debugger for Microsoft
- Testing a Procedure
- Starting the Debugging Session
- Breakpoints
- Step Into
- Step Out
- Correcting the Script

Getting Started with Embarcadero SQL Debugger for Microsoft

This part of Debugging the Sample Script explains how to create the following two procedures to be used for debugging:

- check_modulo
- calculate_sum_with_overflow_bug

**Note:** The procedure calculate_sum_with_overflow_bug intentionally includes a bug which prevents it from executing successfully. You will use the Embarcadero SQL Debugger for Microsoft to identify this bug.

The Getting Started section includes:

- Creating Procedure 1
- Creating Procedure 2
- Confirming the Creation of the Procedures
Creating Procedure 1

Procedure 1, check_modulo, calculates the modulo of any two user-specified numbers. The user passes the numbers into the procedure as input parameters. The procedure returns the result as an output parameter. If the modulo equals zero, procedure execution returns the output “YES”. If the modulo is not zero, procedure execution returns the output “NO”. This procedure is nested in the second procedure, calculate_sum_with_overflow_bug.

To create this procedure, connect to a MSSQL datasource, open a new SQL editor and, in the SQL editor, type or copy and paste the following code:

```sql
CREATE PROCEDURE username.check_modulo
    @p_dividend_in INT,
    @p_divisor_in INT,
    @RESULT VARCHAR(3) OUTPUT
AS
    IF @p_dividend_in % @p_divisor_in = 0
        SELECT @RESULT = 'YES'
    ELSE
        SELECT @RESULT = 'NO'
GO
```

Note: For the purposes of this walk-through, this procedure was created under the user name Spence. Before executing the DDL above, substitute your user name for the word “username”.

1. Connect to a Microsoft SQL Server datasource.
2. On the Datasource menu, select the database node, and then select the target database.

Note: For this walk-through, we recommend that you select a non-production database.

3. On the Main toolbar, click New.

OR

Press CTRL+N.

An SQL Editor opens in the current workspace.

4. In the SQL Editor, type the DDL for procedure check_modulo.

Note: Substitute your user name once in the DDL for this procedure.

5. On the SQL Editor toolbar, click Execute.

The script executes and creates Procedure 1, then opens the SQL Editor Results tab with the results of the script execution. If you were not able to create the procedure, check the error messages to determine the problem.
Creating Procedure 2

Procedure 2, calculate_sum_with_overflow_bug, requires two user-specified numbers as input parameters. Upon execution, the procedure calculates the sum of all numbers divisible by five between the two user-specified numbers. This procedure calls sample procedure 1 (check_modulo) to calculate the modulo of the user-specified numbers.

Note: The procedure calculate_sum_with_overflow_bug intentionally includes a bug which prevents it from executing successfully. You will use the Embarcadero SQL Debugger for Microsoft to identify this bug.

Caution: When you input parameters, enter the smaller number in the @p_num1_in int box.

To create this procedure, connect to a MSSQL datasource, open a new SQL editor and, in the SQL editor, type or copy and paste the following code:

```sql
CREATE PROCEDURE username.calculate_sum_with_overflow_bug
@p_num1_in INT,
@p_num2_in INT,
@RESULT TINYINT OUTPUT
/*INT-Integer (whole number) data from -2^31 (-2,147,483,648) through 2^31 - 1 (2,147,483,647).
TINYINT-Integer data from 0 through 255.*/
AS
DECLARE @temp INT
DECLARE @temp_1 INT
DECLARE @v_divisor INT
DECLARE @v_condition VARCHAR(3)
SET @temp = @p_num1_in
SET @temp_1 = 0
SET @v_divisor = 5
SET @v_condition = 'NO'
WHILE 1=1
BEGIN
    SELECT @temp = @temp + 1 /*Increase temp starting from p_num1*/
    IF @temp = @p_num2_in /*Check if we reached p_num2*/
        /*If yes, leave the LOOP*/
        BREAK
    /*Call Procedure 2 to check if number is divisible by 5*/
    EXEC username.check_modulo @temp,@v_divisor,@RESULT=@v_condition output
    IF @v_condition = 'YES'
        SELECT @temp_1 = @temp_1 + @temp
END /*WHILE LOOP*/
SELECT @RESULT = @temp_1
RETURN
GO
```
Debugging a Sample Script with Embarcadero SQL Debugger for Microsoft

**Note:** For the purposes of this walk-through, this procedure was created under the user name Spence. Before executing the DDL above, substitute your user name for the word “username”.

**Creating Procedure 2**

1. Connect to a Microsoft SQL Server datasource.

2. On the **Datasource** menu, select the database node, and then select the target database.

**Note:** For this walk-through, we recommend that you select a non-production database.

3. On the Main toolbar, click **New**.

OR

Press CTRL+N.

An SQL Editor opens in the current workspace.

4. In the SQL Editor, type the DDL for procedure `calculate_sum_with_overflow_bug`.

**Note:** Substitute your user name twice in the DDL for this procedure.

5. On the SQL Editor toolbar, click **Execute**.

The script executes and creates Procedure 2, then opens the **SQL Editor Results** tab with the results of the script execution. If you were not able to create the procedure, check the error messages to determine the problem.

**Confirming the Creation of the Procedures**

After you create Procedure 1 and Procedure 2, you can confirm their creation in the Datasource Navigator/Explorer.

**Confirming the Creation of the Procedures**

To confirm the creation of the procedures, do the following:

1. On the **Navigator/Explorer** tab, click the Navigator/Explorer list, and then click **Organize By Owner**.

The **Navigator/Explorer** tab refreshes with the new display configuration.

2. On the **Navigator/Explorer** tab, double-click the **Databases** node, and then double-click the target database node.

The list of object owners is displayed.

3. Double-click your user name to display a list of your objects.

4. Double-click **Procedures** to display a list of procedures and confirm the creation of `check_modulo` and `calculate_sum_with_overflow_bug`.
Testing a Procedure

After you confirm the creation of the procedures, execute the procedure `calculate_sum_with_overflow_bug` (which includes a bug) to view its error message. This procedure requires two integer input parameters: `@p_num1_in int` and `@p_num2_in int`. For all integers between these two integers, this procedure identifies those divisible by 5, and then returns their sum.

**Caution:** When inputting parameters, enter the smaller number in the `@p_num1_in int` box.

Testing a Procedure

To test a procedure, do the following:

1. On the **Navigator/Explorer** tab, right-click `calculate_sum_with_overflow_bug`, and then click **Execute**.

The Procedure Execution window opens.

2. In the Value column of the `@p_num1_in` row, type 1.

3. In the Value column of the `@p_num2_in` row, type 11.

4. Click **Execute**.

The procedure is compiled a **Results** tab opens, displaying the sum 15. There are two numbers between 1 and 11 that are divisible by 5: 5, and 10. The sum of these two numbers is 15.

5. On the **Navigator/Explorer** tab, right-click `calculate_sum_with_overflow_bug`, and then click **Execute**.

The Procedure Execution window opens.

6. In the Value column of the `@p_num1_in` row, type 100.

7. In the Value column of the `@p_num2_in` row, type 121.

8. On the Procedure Execution window toolbar, click **Execute**.

The error returned states “Arithmetic overflow occurred”.

Starting the Debugging Session

After you test the procedure, open the procedure in Embarcadero SQL Debugger for Microsoft and enter input parameters before debugging.

To start the debugging session, do the following:

1. On the **Navigator/Explorer** tab, right-click the procedure, `calculate_sum_with_overflow_bug`, and then click **Debug** to start the debug session.
The DDL for the procedure is extracted into a DDL Editor and opens the Procedure Execution dialog.

2. In the Value column of the @p_num1_in row, type 100.
3. In the Value column of the @p_num2_in row, type 121.
4. Click Continue.

The dialog box closes.

The Embarcadero SQL Debugger includes the following five windows:

- DDL Editor Window
- Watch Window
- Variables Window
- Call Stack Window
- Dependency Tree Window

**Breakpoints**

After you start the debugging session, insert a breakpoint into the code of the procedure calculate_sum_with_overflow_bug. Then run to the breakpoint. After you run to the breakpoint, Embarcadero SQL Debugger displays a yellow arrow on the red breakpoint icon and populates the Variables Window with values for the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>@temp</td>
<td>Current number</td>
</tr>
<tr>
<td>@p_num2_in</td>
<td>Second input parameter</td>
</tr>
<tr>
<td>@p_num1_in</td>
<td>First input parameter</td>
</tr>
<tr>
<td>@temp_1</td>
<td>Sum of the numbers, between the input parameters, divisible by 5</td>
</tr>
<tr>
<td>@result</td>
<td>Condition of the output parameter</td>
</tr>
<tr>
<td>@v_condition</td>
<td>Output parameter</td>
</tr>
<tr>
<td>@v_divisor</td>
<td>Divisor</td>
</tr>
</tbody>
</table>

1. In the DDL Editor, scroll to and click the following line:

   EXEC username.check_modulo @temp,@v_divisor,@result=@v_condition output

   **Note:** This line is located near the end of the procedure’s code.

2. On the **Debug** menu, select **Breakpoint**.
3. On the **Debug** menu, select **Go**.

**OR**

Press F5.

Embarcadero SQL Debugger for Microsoft displays the value of the variables before the breakpoint in the Variables Window.

**Step Into**

After setting the breakpoint, step into the dependent procedure, check_modulo.

To use the Step Into facility, do the following:

1. On the **Debug** menu, select **Step Into**.

**OR**

Press F11.

The DDL for the dependent, nested procedure is extracted into the DDL Editor.

2. Step Into again.

The next part of the code executes and displays the values for the variables in the Variables Window.

The Call Stack Window displays calls to the procedures.

**Step Out**

After you Step Into the modulo_check (nested procedure) code, step back out and return to the calculate_sum_with_overflow_bug (outside procedure) code.

To use the Step Out facility, do the following:

1. On the **Debug** menu, select **Step Out**.

**OR**

Press SHIFT+F11.

The DDL Editor opens, containing the code for calculate_sum_with_overflow_bug.

2. On the **Debug** menu, select **Go**.

**OR**

Press F5.
When the value of the variable, @temp is equal to the value of the variable, @p_num2_in, the WHILE LOOP is complete and the Embarcadero SQL Debugger for Microsoft continues to the next executable statement in the code.

3. While monitoring the value of the variables in the Variables Window, continue to click Go to cycle through the WHILE LOOP.

After executing the SELECT and RETURN statements, the Debugger closes a DDL Editor opens to the Results tab.

Correcting the Script

When you finished Stepping Out of the nested code and encounter the error, to fully fix the bug, do the following:

1. Locate the source of the error
2. Scroll to the line in the script displaying the error
3. Analyze the code
4. Correct the error
5. Compile the corrected script

When you first executed the procedure, the error message “Arithmetic overflow error for data type tinyint, value = 450” was displayed. According to Microsoft SQL Server Books Online: “This error occurs when an attempt is made to convert a float or real data type value into a data type that cannot store the result. This error prevents the operation from being completed.”

The data type used in this procedure (TINYINT) stores values from 0 to 255. The sum of the four numbers between 100 and 121 that are divisible by 5 (105, 110, 115, and 120) is 450. But because the TINYINT variable @result can only accept a maximum value of 255, the error message was returned and the procedure fails.

To correct the script, do the following:

1. On the Navigator/Explorer tab, right-click calculate_sum_with_overflow_bug, and then click Extract.

The DDL for the procedure is extracted into a DDL Editor.

2. On the Edit toolbar, click Find.

The Find dialog opens.

3. In the Find What box, type TINYINT.

4. Click Find Next.

The first occurrence of TINYINT is selected.

5. Change the data type for @result from TINYINT to INT.
6. On the DDL Editor toolbar, click **Execute** to execute the modified script.

The script executes and the **Results** tab opens.

7. On the **Navigator/Explorer** tab, right-click `calculate_sum_with_overflow_bug`, and then click **Execute**.

The **Procedure Execution** dialog opens.

8. In the Value column of the @p_num1_in row, type 100.

9. In the Value column of the @p_num2_in row, type 121.

10. Click **Execute**.

The procedure executes with the new data type and opens the **Results** tab, returning the value 450. You successfully corrected the script and debugged the procedure.
Debugging a Sample Script with Embarcadero SQL Debugger for Oracle

The installation includes a sample script intended to walk you through basic debugging functionality. The sample script creates a package that includes functions and procedures that you debug.

**Note:** To create the sample package, you must have CREATE privileges.

**Overview**

Debugging a Sample Script is divided into three sections that familiarize you with basic debugging features and functionality:

- **Getting Started with Embarcadero SQL Debugger for Oracle** guides you through creating the package you use in Debugging Sample Script 1 and Debugging Sample Script 2.
- **Debugging Sample Script 1** guides you through debugging functionality and demonstrates the Embarcadero SQL Debugger for Oracle interface features.
- **Debugging Sample Script 2** guides you through debugging functionality and demonstrates the Embarcadero SQL Debugger for Oracle interface features.

**Note:** For the purposes of this walk-through we have created this package under the user name DEMO_SPENCE.

**Getting Started with Embarcadero SQL Debugger for Oracle**

The installation includes a sample script that you execute to create a package containing functions and procedures. These functions and procedures demonstrate basic debugging features available in the Embarcadero SQL Debugger for Oracle.

**Note:** To create the sample package, you must have CREATE privileges.

On installation the script is placed in the \UsrScript subfolder of the main installation directory.

If you create the package included with the installation, you can delete it and its objects from your system when you finish working with them. The objects to delete:

- The package COUNT_TIME_INTERVAL
- The package function WEEKEND_DAYS_( )
- The package function WORKING_DAYS_( )
- The package function YEARS_ELAPSED_BETWEEN_( )
- The procedure YEARS_ELAPSED
The procedure YEARS_ELAPSED_Y2K

**Embarcadero SQL Debugger for Oracle Overview**

The Getting Started section guides you through:

- Opening the sample debug script.
- Executing sample debug script.
- Changing the **Navigator/Explorer** tab display.
- Confirming the creation of the package, including its functions and procedures.

**Getting Started**

1. On the **File** menu, select **Open**.

The **Open File(s)** dialog opens.

2. In the **Open File(s)** dialog, go to DBA900\UsrScrpt\DEBUGGER_DEMO.sql, and then click **Open**.

**Note:** During the installation the DEBUGGER_DEMO.sql is placed in the \UsrScrpt subfolder of the main installation folder.

The **What type of file** dialog opens.

3. On the **What type of file** dialog, click **The file includes the DDL to create a database object**, and then click **OK**.

The target script opens in an SQL Editor.

4. On the SQL Editor toolbar, click **Execute** to execute the script and create the package.

The target script executes and opens the SQL Editor **Results** tab, displaying the results of the script execution. If you were not able to create the package, check the error messages to determine the problem.

5. On the **Navigator/Explorer** tab list, click **Organize by Owner**.

A list of owners is displayed.

6. On the Navigator/Explorer, double-click your owner name.

A list of your schema objects is displayed.

7. Under your owner node, double-click the **Packages** node.

A COUNT_TIME_INTERVAL displayed, confirming the package’s creation.
Debugging Sample Script 1

Sample Script 1 demonstrates Embarcadero SQL Debugger’s basic features and functionality with the function WORKING_DAYS( ), which counts the number of business days between two dates.

Debugging Sample Script 1 is divided into five parts:

- Sample Script 1 - Starting the Debug Session
- Sample Script 1 - Entering Input Parameters
- Sample Script 1 - Viewing Debug Session Results

Sample Script 1 - Starting the Debug Session

After you open and execute DEBUGGER_DEMO.sql, you can begin debugging Sample Script 1. To begin debugging the function WORKING_DAYS( ), start a debug session.

Starting the Debug Session

To start the debug session, do the following:

1. On the Navigator/Explorer tab, under the Packages node, double-click the COUNT_TIME_INTERVAL node.

The COUNT_TIME_INTERVAL node opens and displays the following items:

2. Under the COUNT_TIME_INTERVAL node, double-click Functions.

The Functions node opens and displays the following items:

3. Under the Functions node, right-click WORKING_DAYS ( ), and then click Debug to start the debug session.

The Function Execution dialog opens with the current date in the boxes.

Sample Script 1 - Entering Input Parameters

After you start a debugging session, you can enter input parameters. You cannot debug a script that requires input parameters until you input those parameters in the Function Execution dialog.

Input Parameters

To enter input parameters, do the following:

1. Click the P_START_DATE DATE box, and then click the drop-down arrow.

A calendar opens.

2. On the calendar, click the left arrow to set the month to November 1999.

3. Click 1.
11/01/1999 is displayed in the Value column of P_START_DATE.

4. Click the P_END_DATE DATE box, and then click the drop-down arrow.

A new calendar opens.

5. On the calendar, click the left arrow to set the month to November 1999.

6. Click 8.

11/08/1999 is displayed in the Value column of P_END_DATE.

7. Click OK.

The Function Execution dialog closes and then opens the following five Embarcadero SQL Debugger for Oracle interface windows:

- DDL Editor Window, which displays the SQL code for the function.
- Watch Window
- Variables Window
- Call Stack Window
- Dependency Tree Window, which displays the dependent objects.

Sample Script 1- Inserting Breakpoints

After you input parameters in the Input Parameters dialog, you can begin inserting breakpoints. In this example, you insert the breakpoints in the extracted dependent object code. After you extract this code, locate the target breakpoint lines by searching for the text DBMS_OUTPUT.

Breakpoints

To insert breakpoints, do the following:

1. In the Dependency Tree window, double-click the COUNT_TIME_INTERVAL package body.

The SQL code for the package body opens in the SQL Editor window.

2. On the Edit toolbar, click Find.

The Find dialog opens.

3. On the Find dialog, in the Find What box, type DBMS_OUTPUT.

4. Click Find Next.

In the SQL Editor, the first occurrence of DBMS_OUTPUT, on line 22 is highlighted.

5. On the SQL Editor toolbar, click Breakpoint.

A breakpoint is inserted next to the target line number.
6. On the Find dialog, click Find Next. The next occurrence of DBMS_OUTPUT is highlighted.

7. Click Find Next a third time. The next occurrence of DBMS_OUTPUT, on line 35, is highlighted.

9. On the Edit toolbar, click Breakpoint to insert a second breakpoint.

You should now have breakpoints set at lines 22 and 35.

Sample Script 1- Stepping Into

After you insert breakpoints, you can step into the function code.

Step Into

To use the Step Into facility, do the following:

1. On the SQL Editor toolbar, click Go. Embarcadero SQL Debugger for Oracle begins debugging and runs to the first breakpoint, placing the yellow arrow on line 22.

2. On the SQL Editor toolbar, click Step Into. Embarcadero SQL Debugger for Oracle moves the yellow arrow to the next line of the code.

3. Click Step Into again to enter the LOOP block. Embarcadero SQL Debugger for Oracle displays the value of the variables in the Variables window.

4. Click Step Into again to start moving through the LOOP block. In the Variables window, Embarcadero SQL Debugger for Oracle updates the value of variable v_curdate from 01-NOV-1999 to 02-NOV-1999.

5. Click Step Into two more times. In the Variables window, Embarcadero SQL Debugger for Oracle updates the value of v_theday from NULL to Tuesday.

Note: If you continued stepping through the LOOP block, the Embarcadero SQL Debugger for Oracle would continue to update v_curdate and v_theday until v_curdate is greater than p_end_date.

6. On the SQL Editor toolbar, click Go. Embarcadero SQL Debugger runs to the next breakpoint.
7. On the SQL Editor toolbar, click **Go** once more.

Embarcadero SQL concludes the debug session and displays the Debug Session Results box.

**Sample Script 1 - Viewing Debug Session Results**

After Stepping Into and running to the end of the code, Embarcadero SQL Debugger for Oracle displays a Debug Session Results box containing the following information:

- Variable Output
- DBMS_OUTPUT Results

**Note:** In this example, the Embarcadero SQL Debugger for Oracle displays a Debug Session Results box because the sample program includes DBMS_OUTPUT.

**Debug Session Results**

To debug session results, do the following:

1. Click **OK**.

The Debug Session Results box closes and your debug session terminates.

**Debugging Sample Script 2**

Sample Script 2 demonstrates Embarcadero SQL Debugger for Oracle’s functionality when used on a function containing a bug which prevents it from executing successfully. The buggy function, WEEKEND_DAYS(), requires input parameters and counts the number of weekend days between two dates. In this section, use Embarcadero SQL Debugger for Oracle to identify the bug, and then correct the script so that it can execute successfully.

Debugging Sample Script 2 is divided into six parts:

- **Sample Script 2 - Executing the Function**
- **Sample Script 2 - Starting the Debug Session**
- **Sample Script 2 - Entering Input Parameters**
- **Sample Script 2 - Inserting Breakpoints**
- **Sample Script 2 - Stepping Into**
- **Sample Script 2 - Correcting the Script**

**Sample Script 2 - Executing the Function**

After you open and execute DEBUGGER_DEMO.sql, you can begin debugging Sample Script 2. To begin debugging the function WEEKEND_DAYS(), first execute the function to discover the type of error it returns when it fails to execute.
Executing the Function

To execute the function, do the following:

1. On the Navigator/Explorer tab, under the Packages node, double-click the COUNT_TIME_INTERVAL node.

The COUNT_TIME_INTERVAL node opens.

2. Double-click the Functions node.

The Functions node opens.

3. Click WEEKEND_DAYS (), then right-click it and click Execute.

The Function Execution dialog opens.

4. In the Value column of the P_START_DATE row, type 11/01/1999.

5. In the Value column of the P_END_DATE row, type 11/30/1999.

6. Click Execute.

The attempt to execute the function fails and returns an error indicating that the character string buffer is too small.

Sample Script 2 - Starting the Debug Session

After you unsuccessfully execute the function WEEKEND_DAYS() and determine the nature of its execution error, you can start a debugging session to determine the actual cause of the error.

Starting the Debugging Session

To start the debugging session, do the following:

1. On the Navigator/Explorer tab, under the COUNT_TIME_INTERVAL node, under the Functions node, right-click WEEKEND_DAYS (), and then click Debug to start the debug session.

The Function Execution dialog opens.

Sample Script 2 - Entering Input Parameters

After you start the debug session, you can enter input parameters in the Function Execution dialog.

Entering Input Parameters

To enter input parameters, do the following:

1. At the end of the P_START_DATE row, click the drop-down arrow.

The calendar opens.
2. On the calendar, click Left Arrow to set the month to **November 1999**.
3. Click 1.

**11/01/1999** is displayed in the **Value** column of the **P_START_DATE** row.
4. At the end of the **P_END_DATE** row, click the drop-down arrow.

A new calendar opens.
5. On the calendar, click Left Arrow to set the month to **November 1999**.
6. Click **30**.

**11/08/1999** is displayed in the **Value** column of the **P_END_DATE** row.
7. Click Continue.

The **Function Execution** dialog closes and then opens the following five Embarcadero SQL Debugger for Oracle interface windows:

- **DDL Editor Window**, which displays the SQL code for the function
- **Watch Window**
- **Variables Window**
- **Call Stack Window**
- **Dependency Tree Window**, which displays the dependent objects.

**Sample Script 2- Inserting Breakpoints**

After you enter input parameters, you can begin inserting breakpoints. In this example, you insert the breakpoints in the extracted dependent object code. After you extract this code, locate the target breakpoint lines by searching for a particular line of code.

**Breakpoints**

To insert breakpoints, do the following:

1. In the **Dependency Tree** window, double-click the **COUNT_TIME_INTERVAL** package body.

The SQL code for the package body opens in the SQL Editor.
2. On the **Edit** toolbar, click **Find**.

The **Find** dialog opens.
3. On the **Find** dialog, in the **Find What** box, type **Function weekend_days**, and then click **Find Next**.

Embarcadero SQL Debugger for Oracle highlights the first occurrence of Function weekend_days.
4. On the Find dialog, click Cancel.

The Find dialog closes.

5. Click line 60, the first line of executable code:

6. On the SQL Editor toolbar, click Breakpoint.

A breakpoint is inserted next to the line number.

7. Click Go to start debugging and run to the breakpoint.

Embarcadero SQL Debugger for Oracle places the yellow arrow on line 60 and populates the Variables window with the first set of variables in the function code.

Embarcadero SQL Debugger for Oracle also populates the Call Stack window with everything called before the breakpoint.

**Sample Script 2- Stepping Into**

After you set and run to the breakpoint, you can step into the function to locate the cause of the error. To locate the cause of the error, monitor the Variables window. As you step through the code, the Variables window updates with the value of the variables.

**Step Into**

1. On the SQL Editor toolbar, click Step Into.

The yellow arrow moves to the next line of the code, line 64.

2. On the SQL Editor toolbar, click Step Into.

Embarcadero SQL Debugger for Oracle’s Variables window updates the value of v_currdate to 02-NOV-1999.

3. On the SQL Editor toolbar, click Step Into.

The yellow arrow moves to the next line of the code, line 66.

4. On the SQL Editor toolbar, click Step Into.

The yellow arrow moves to the next line of the code, line 67, and, in the Variables window, updates the value of v_theday to Tuesday.

5. On the SQL Editor toolbar, click Step Into.

The yellow arrow moves back to line 64 to repeat the loop.

6. On the SQL Editor toolbar, click Step Into.

Embarcadero SQL Debugger for Oracle’s Variables window updates the value of v_currdate to 03-NOV-1999.

7. On the SQL Editor toolbar, click Step Into.
The yellow arrow moves to the next line of the code, line 66.

8. On the SQL Editor toolbar, click **Step Into**.

The Embarcadero SQL Debugger for Oracle locates the error. The application terminates the debug session, returns an error indicating that the numeric or value character string buffer is too small, extracts the COUNT_TIME_INTERVAL package code into an SQL Editor, and returns an error indicating the line on which the code failed.

**Sample Script 2 - Correcting the Script**

After you step through the SQL code and locate the error, you can correct the bug in Sample Script 2. When Embarcadero SQL Debugger for Oracle locates an error, it extracts the target package body into an SQL Editor. To correct this script:

- Scroll to the incorrect line in the script
- Analyze the code
- Correct the error
- Execute the corrected SQL script
- Execute the WEEKEND_DAYS ( ) function

The code in Sample Script 2 fails on line 66, returning an error when the variable **v_theday** increments from the value **Tuesday** to the value **Wednesday**. The cause of this error is found in the declarations section of the function script, where the width of the VARCHAR2 variable **v_theday** is set to **8**. Because **Wednesday** includes nine characters, the value of the variable **v_theday** fails when it attempts to place a nine-character value in an eight-character variable. To correct this error, increase the width of the variable **v_theday** to accommodate nine characters.

**Correcting the Script**

To correct the script, do the following:

1. On the **Navigator/Explorer** tab, under the **Packages** node, under the COUNT_TIME_INTERVAL node, right-click **Package Body**, and then click **Extract**.

The package body is extracted into an SQL Editor.

2. In the SQL Editor, scroll to line 57, the line defining the variable **v_theday**.

3. On line 57, change the value of the width from **8** to **9**.

4. On the SQL Editor toolbar, click **Execute** to execute the script.

The script executes successfully.

5. On the **Navigator/Explorer** tab, under the COUNT_TIME_INTERVAL package node, under the **Functions** node, click **WEEKEND_DAYS ( )**.

6. Right-click **WEEKEND_DAYS ( )**, and then click **Execute**.
The **Function Execution** dialog opens.

7. In the **Value** column of the **P_START_DATE** row, type **11/01/1999**.

8. In the **Value** column of the **P_END_DATE** row, type **11/30/1999**.

9. Click **Execute**.

The corrected function executes successfully.
PL/SQL Profiler

The PL/SQL Profiler module lets Oracle developers capture metrics of various PL/SQL programmable objects as they are executed in the database. Developers can use data collected in profile sessions to improve performance of PL/SQL code execution. The PL/SQL Profiler collects and stores data in database tables that let you identify and isolate performance problems and provide code coverage information. The PL/SQL Profiler lets you:

- Graphically browse PL/SQL profiling data within the Explorer Tab
- View profiling data in the right pane of the application, which is populated as you navigate the Explorer Tab
- Start and stop PL/SQL profiling sessions with a single click
- Graphically analyze time spent in each programmable object (unit)
- Graphically analyze time spent in each source code line of a unit

Requirements

- Oracle built-in package DBMS_PROFILER
- Oracle tables:
  - PLSQL_PROFILER_RUNS
  - PLSQL_PROFILER_UNITS
  - PLSQL_PROFILER_DATA (user’s schema)

The table below describes the sections of this chapter:

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Setting up PL/SQL Profiler</td>
<td>Describes the process of setting up the PL/SQL Profiler.</td>
</tr>
<tr>
<td>PL/SQL Profiler Functionality</td>
<td>Describes the functionality of the PL/SQL Profiler.</td>
</tr>
<tr>
<td>Using PL/SQL Profiler</td>
<td>Describes how to run a profile session.</td>
</tr>
</tbody>
</table>

**Note:** The PL/SQL Profiler is an optional add-on module.

**Topics**

- Setting up PL/SQL Profiler
- PL/SQL Profiler Explorer
- PL/SQL Profiler Functionality
- Using PL/SQL Profiler
Setting up PL/SQL Profiler

The Oracle profiling tables must be on the Oracle server before you can use the PL/SQL Profiler. The first time you open the PL/SQL Profiler, the server is checked for the profiling tables. If the profiling tables are not on the server, Oracle SQL*Plus is started, which installs profiling tables on the Oracle server.

To run Oracle SQL*Plus (which installs the profiling tables) your Oracle server and client must meet the following conditions:

- The Oracle server and the client have the same version of Oracle.
- The client has the Oracle\BIN directory on the path.
- The client has the Oracle file, SQLPLUS.exe in the Oracle\BIN directory.
- The following Oracle files are in the Oracle\RDBMS\ADMIN directory:
  - DBMSPBP.sql
  - PROFLOAD.sql
  - PROFTAB.sql
  - PRVTPBP.blp

Note: If the Oracle server and the client machines are running different versions of Oracle, after running SQL*Plus, the following error message is displayed: Version of package is incompatible.
The PL/SQL Profiler displays profiling data in the right pane of the application, which is populated as you navigate the Explorer tab.

The table below describes the nodes of the PL/SQL Profiler Explorer and the corresponding information in the right pane of the application:

<table>
<thead>
<tr>
<th>Node</th>
<th>Right pane information</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL/SQL Code</td>
<td>Contain all Comment, Run ID and Run Date\time data that is currently stored in the Profiling tables.</td>
</tr>
<tr>
<td>Profiling</td>
<td></td>
</tr>
<tr>
<td>Label\Comment</td>
<td>Contains all Run ID and Run Date\time data for the specific Label\Comment.</td>
</tr>
<tr>
<td>level</td>
<td></td>
</tr>
<tr>
<td>Run level</td>
<td>Contains all Unit, Unit Name, Unit Type, Run Date\time data for the specific Run ID.</td>
</tr>
</tbody>
</table>
PL/SQL Profiler Functionality

The PL/SQL Profiler offers the following functionality:

- Start
- Flush
- Run Summary
- Run Detail
- Unit Summary
- Clear Profile Table
- Unit Detail
- Stop (PL/SQL Profiler)
Start

You begin a new profiling session or open a previous profiling session with the Start command.

Starting a New Profile Session

To start a new profile session, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Start.
   
The PL/SQL Profiler - Start dialog opens.

2. In the Profile Label box, type the name of the new profile.
   
   Note: Each user can own one or more Profiles.

3. Click OK.

   Profiling begins.

Starting an Existing Profile Session

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Start.

   The PL/SQL Profiler - Start dialog opens.

2. Click the Profile Label list, and then click the existing profile.

3. Click OK.

   Profiling begins.

Topics

- PL/SQL Profiler Functionality
Flush

The PL/SQL Profiler lets you move the data from the dynamic tables into analysis tables with the flush command.

The table below describes the options and functionality on the PL/SQL Profiler - Flush dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flush</td>
<td>Click to delete the data in a running profile.</td>
</tr>
<tr>
<td>Flush &amp; Analyze</td>
<td>Click to open the PL/SQL Profiler Run Detail window. For details, see Run Detail.</td>
</tr>
<tr>
<td>Cancel Button</td>
<td>Click to abort the flush and continue the profiling session.</td>
</tr>
</tbody>
</table>

Note: You can only Flush a running Profile.

Flushing a Profile

To flush a profile, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Flush.

The PL/SQL Profiler - Flush dialog opens.

Topics

- PL/SQL Profiler Functionality
Run Summary

The PL/SQL Profiler Run Summary window lets you to view the following information for each of your profiles:

- Run ID
- Run Date
- Total Time

Opening the Run Summary Window

To open the Run Summary Window, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Run Summary.

   The PL/SQL Profiler - Run Summary window opens.

2. In the PL/SQL Profiler - Run Summary window, click the Label list, and then click the target profile to populate the table.

Topics

- PL/SQL Profiler Functionality
Run Detail

The PL/SQL Profiler Run Detail window lets you to view the following information for each of your profiles:

- Run Number
- Run Date
- Run Time

The Run Detail tab lets you:

- View the information for all runs or you can view profile information based on the unit type or unit owner.
- View results in milliseconds, seconds and minutes.
- View graphical displays of the profiling data that let you can navigate to the specific unit within the summary portion of the window.
- Specify the number of top lines to display in the graphical portion of the interface.

Tip: Each graph is a working object. You can select data in a graph and the corresponding line of source displays in the lower pane of the interface.

Opening the Run Detail Window

To open the Run Detail Window, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Run Detail.

The PL/SQL Profiler - Run Detail window opens.

2. In the PL/SQL Profiler - Run Detail window:
   - Click the Label list box, and then click the target profile.
   - Click the Run list, and then click the target run.
   - Click the Unit Type list, and then click the target unit type(s).
   - Click the Unit Owner list, and then click the target unit owner(s) to populate the table.

Topics

- PL/SQL Profiler Functionality
Unit Summary

The PL/SQL Profiler Unit Summary window lets you to view the following information for each of your profiles:

- Run ID
- Run Date
- Run Time
- Unit Time
- Percentage of Run Time

The PL/SQL Profiler Unit Summary window lets you view results in milliseconds, seconds and minutes. The Unit Summary window also displays graphs of execution statistics for the top N runs and associated units. You can use the graphical displays to navigate to the specific run within summary portion of the window.

Opening the Unit Summary Window

To open the Unit Summary Window, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Unit Summary.
   The PL/SQL Profiler - Unit Summary window opens.

2. In the PL/SQL Profiler - Unit Summary window:
   - Click the Unit Owner list, and then click the target unit owner.
   - Click the Unit Name list, and then click the target unit name to populate the table.

Topics

- PL/SQL Profiler Functionality
Clear Profile Table

The PL/SQL Profiler lets you delete data from the user’s profile tables with the command Clear Profile Table.

Clearing a Profile Table

To clear a Profile Table, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Clear Profile Table.

   The profile table is cleared.

2. If you are sure that you want to clear out the profiler tables, click Yes.

Topics

- PL/SQL Profiler Functionality
Unit Detail

The PL/SQL Profiler Unit Detail window lets you to view the following information for each of your profiles:

- Average Time
- Source
- PL/SQL Script

The PL/SQL Profiler Unit Detail window lets you view results in milliseconds, seconds and minutes. The Unit Detail window also provides two calculation options for viewing unit execution time as a percentage of total execution time (total run vs unit run). Additionally, also displays graphs of execution statistics for the top N run. You can use the graphical displays to navigate to the specific line within source code portion of the window. The graphical display portion of the window contains options for viewing advanced statistics.

The Advanced View of the PL/SQL Profiler Unit Detail window lets you view the following information for each of your profiles:

- Hit Lines
- Missed Lines
- Line Number
- Calls
- Total Time
- Percentage of the Total Time
- Average Time
- Minimum Time
- Maximum Time

Opening the Unit Detail Window

To open the Unit Detail Window, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Unit Detail.

   The PL/SQL Profiler - Unit Detail window opens.

2. In the PL/SQL Profiler - Unit Detail window, do any of the following:
   - Click the Label list, and then click the target profile.
   - Click the Run list, and then click the target run.
   - Click the Unit list, and then click the target unit to populate the table.
Unit Detail

- Right-click, and then click Show Only Hit Lines to populate the table with the Average Time and Source for hit lines.
- Right-click, and then click Show Only Missed Lines to populate the table with the Average Time and Source for missed lines.

Opening the Unit Detail Window Advanced View

To open the Unit Detail Window Advanced View, do the following:

1. In the Unit Detail window, right-click, and then click Advanced View to populate the table with Advanced View information.

Topics

- PL/SQL Profiler Functionality
Stop (PL/SQL Profiler)

The PL/SQL Profiler Stop command pauses the data gathering operation. Stop & Analyze populates the summary tables so that you can view the Unit Detail and Run Summary windows.

The table below describes the options and functionality on the PL/SQL Profiler - Stop dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop</td>
<td>Click to stop the profiling session.</td>
</tr>
<tr>
<td>Stop &amp; Analyze</td>
<td>For details, see Run Detail.</td>
</tr>
<tr>
<td>Cancel</td>
<td>Click to continue the profiling session.</td>
</tr>
</tbody>
</table>

Stopping a Profiling Session

To stop a Profiling Session, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Stop.

The PL/SQL Profiler - Stop dialog opens.

Topics

- PL/SQL Profiler Functionality
Using PL/SQL Profiler

The steps in this section provide a high level overview of running a profiling session, and cover the following processes:

- Starting the Session.
- Executing the Sample Script.
- Stopping and Analyzing the Session.

Note: The first execution of a PL/SQL unit can take more time to execute because the code is loading into memory; subsequent runs take less time.

Using the PL/SQL Profiler

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Start.

The PL/SQL Profiler - Start dialog opens.

2. In the Profile Label box, type the name of the new profile.

Note: Each user can own one or more Profiles.

3. Click OK.

Profiling begins.

4. On the Datasource Navigator/Explorer, execute on one of the following PL/SQL database objects:
   - Procedure
   - Function
   - Package Procedure
   - Package Function

Profiler displays profiling data in the right pane of the application.

5. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Stop.

The PL/SQL Profiler - Stop dialog opens.

The table below describes the options and functionality on the PL/SQL Profiler - Stop dialog:
Using PL/SQL Profiler

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop</td>
<td>Click to stop the profiling session.</td>
</tr>
<tr>
<td>Stop &amp; Analyze</td>
<td>Click to open the <strong>PL/SQL Profiler Run Detail</strong> window. For details, see <a href="#">Run Detail</a>.</td>
</tr>
<tr>
<td></td>
<td>Click the <strong>Label</strong> list, and then click the target profile. Click the <strong>Run</strong> list, and then click</td>
</tr>
<tr>
<td></td>
<td>the target run. Click the <strong>Unit Type</strong> list, and then click the target unit type(s). Click the</td>
</tr>
<tr>
<td></td>
<td><strong>Unit Owner</strong> list, and then click the target unit owner(s) to populate the table.</td>
</tr>
<tr>
<td>Cancel</td>
<td>Click to continue the profiling session.</td>
</tr>
</tbody>
</table>

6. If using DBArtisan, use the **Utilities** menu to open any of the following PL/SQL Profiler windows. For more information, see:

   - [Run Summary](#)
   - [Unit Summary](#)
   - [Unit Detail](#)

**Topics**

- [Sample Profiling Session](#)
- [PL/SQL Profiler Functionality](#)
Sample Profiling Session

The DBArtisan installations include two scripts for the sample profiling session:

- PROFILER_BUILD_DEMO.SQL
- PROFILER_DEMO.SQL

The PROFILER_BUILD_DEMO.SQL creates the objects that you profile in the walk through, and the PROFILER_DEMO.SQL is what you profile during the walk through.

**Note:** To create the objects in the PROFILER_BUILD_DEMO.SQL script, you need CREATE privileges.

The sample script demonstrates the following features of the PL/SQL Profiler:

- Unit Detail
- Run Detail
- Show Only Hit Lines
- Advanced View

The scripts are located in the \UsrScrpt subfolder of the main installation folder.

**Overview**

Sample Profiling Session is divided into six parts:

- Getting Started
- Starting the Session
- Executing the Sample Script
- Stopping the Session
- Re-running & Re-executing the Session
- Stopping & Analyzing

**Sample Profiling Session - Getting Started**

In this step of Sample Profiling Session, you create the objects that you profile in the walk through.

**Overview**

The Getting Started section guides you through:

- Opening PROFILER_BUILD_DEMO.SQL.
- Changing the Datasource Navigator/Explorer Display.
Sample Profiling Session

- Confirming the Creation of the Package.

Getting Started

1. On the File menu, select Open.

The Open Files dialog opens.

2. In the Open Files dialog, navigate to the UsrScrpt subfolder of the main installation folder, press ENTER, and then double-click PROFILER_BUILD_DEMO.SQL to open the script in a SQL Editor window.

The PROFILER_BUILD_DEMO.SQL script opens in an SQL Editor window.

3. On the SQL Editor window, click Execute.

The script executes and creates the package.

4. On the Navigator/Explorer window list, click Organize by Owner.

5. On the Navigator/Explorer window, click the node of your owner name.

Your schema objects are displayed.

6. Double-click the Packages node to display PF_COUNT_TIME_INTERVAL and confirm its creation.

Note: If you were not able to create the package, check the error messages to determine the problem.

Sample Profiling Session - Starting the Session

In this step of Sample Profiling Session, you start the profiling session.

Sample Profiling Session - Starting the Session

To start the session, do the following:

1. On the File menu, select Open.

The Open Files dialog opens.

2. In the Open Files dialog, type the path to the UsrScrpt directory, press ENTER, and then double-click PROFILER_DEMO.SQL.

The script opens in a SQL Editor window.

3. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Start.

The PL/SQL Profiler - Start dialog opens.

4. In the Profile Label list, enter DemoProfile.

5. Click OK.

The profiling session begins.
Note: If this is the first time you start the PL/SQL Profiler, a dialog box opens.

Note: Click Yes to have SQL*Plus create the tables. You need to start the profiling session again (see step 3 above.)

Sample Profiling Session - Executing the Sample Script

In this step of Sample Profiling Session, you execute the DEMO script.

Sample Profiling Session - Executing the Sample Script

To execute the sample script, do the following:

1. On the SQL Editor window toolbar, click Execute.

The script executes and opens a Results tab.

Sample Profiling Session - Stopping the Session

In this step of Sample Profiling Session, you stop the profiling run.

Sample Profiling Session - Stopping the Session

To stop the session, do the following:

1. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Stop.

The PL/SQL Profiler - Stop dialog opens.

2. Click Stop.

Sample Profiling Session - Re-running & Re-executing the Session

In this step of Sample Profiling Session, you run the same profile session and execute the DEMO script again.

Sample Profiling Session - Re-running & Re-executing the Session

To re-run and re-execute the session, do the following:

1. In the SQL Editor, click the Query tab.

2. If using DBArtisan, on the Utilities menu, select PL/SQL Profiler > Start.

The PL/SQL Profiler - Start dialog opens again.

3. Click the down arrow on the Profile Label list, and then click DemoProfile.

4. Click OK.

The profiling session begins.
Sample Profiling Session

5. On the SQL Editor toolbar, click **Execute**. The script executes again and the **Results** tab opens.

**Sample Profiling Session - Stopping & Analyzing**

In this step of Sample Profiling Session, you stop profiling and analyze the runs.

**Sample Profiling Session - Stopping & Analyzing**

To stop and analyze the sample profiling session, do the following:

1. If using DBArtisan, on the **Utilities** menu, select **PL/SQL Profiler > Stop**. The **PL/SQL Profiler - Stop** dialog opens again.
2. Click **Stop & Analyze**. The **PL/SQL Profiler - Run Detail** window opens.
3. Click the **Run** list, and then click **Run#x**.

**Note**: A number is assigned to each profiling session. These numbers increase incrementally each time you run a profiling session. x= the number that was assigned to your first run.

PL/SQL Profiler populates the grid with information on the procedure, package body and package specification.

**Note**: For the purposes of this walk though we have created this package under the account SCOTT.

4. Click the **Run** list again, and then click the **Run#x** for your second run. Notice this time there is no information on the package specification. It was created in the first run.
5. Right-click, and then click **Detail**. The **PL/SQL Profiler - Unit Detail** window opens, the grid is populated with the average time to execute each unit and the source code. Notice the time to execute SELECT object_name, in the example is 126 ms.
6. In the **PL/SQL Profiler - Unit Detail** window, click the **Run** list, and then click **Run#x** for your first run.
7. Click the **Unit** list, and then click **user name.PF_COUNT_SYSTEM_OBJECTS**. Notice the time to execute SELECT object_name is considerably greater: in the example it is 24476 ms.
8. Right-click, and then click **Show Only Hit Lines**. The PL/SQL Profiler shows only the lines of code that executed.
9. Right-click, and then click **Advanced View**.
The Advanced View window opens.

10. Continue clicking the Run and Unit lists to compare the performance of each run and each session.

This concludes the Sample Profiling Session. You can delete the objects created during the Sample Profiling Session. They are:

- Check Constraints, PLSQL_PROFILER_UNITS, PLSQL_PROFILER_DATA
- Foreign Keys, PLSQL_PROFILER_UNITS, PLSQL_PROFILER_DATA
- Package, PF_COUNT_TIME_INTERVAL
- Package functions, WEEKEND_DAYS_(), WORKING_DAYS_(), YEARS_ELAPSED_BETWEEN_()
- PL/SQL code Profiles, DemoProfile
- Primary Keys, PLSQL_PROFILER_RUNS, PLSQL_PROFILER_UNITS, PLSQL_PROFILER_DATA
- Procedure, PF_COUNT_SYSTEM_OBJECTS
- Sequence, PLSQL_PROFILER_RUNNUMBER
- Tables, PLSQL_PROFILER_RUNS, PLSQL_PROFILER_UNITS, PLSQL_PROFILER_DATA
Capacity Analyst

Welcome to the Embarcadero Capacity Analyst. The Capacity Analyst collects critical
database storage, object, and performance metrics at scheduled intervals and provides
visual analysis and reporting mechanisms that allow for historical trend analysis and
forecasting.

Capacity Analyst lets you:

- Create and maintain Capacity Collections that serve as containers for related
  statistics.
- Collect statistics in Capacity Collections.
- View graphic and report-styled presentations of trend and predictive analysis
  scenarios.
- Maintain functions regarding the handling of stored statistics.

The table below describes the major sections of Help.

Getting Started with the Capacity Analyst

Welcome to the Embarcadero Capacity Analyst. The Capacity Analyst helps you analyze current usage trends in your key databases and lets you forecast where your databases are heading in the future.

Licensing Capacity Analyst

Availability of this feature depends on your licensing. For more information, see Licensing.

Opening the Capacity Analyst

Capacity Analyst runs as a tab in the main DBArtisan window.

To open the Capacity Analyst:

1. Start DBArtisan and connect to the datasource that you want to run reports or analysis against. For details, see Connecting to Datasources.

2. From the Analyst menu select Capacity Analyst.

OR

On the Analyst Series toolbar click the Capacity Analyst button.

Capacity Analyst opens, displaying any existing collections.
Capacity Analyst Repository Installation

The Capacity Analyst Repository Installation Wizard lets you install the repository on each database the Capacity Analyst runs against. The repository holds all the captured metrics that you want to collect. For example, this can be the space used in an Oracle tablespace or the number of physical reads on a Microsoft SQL Server.

The wizard installs a set of objects to manage the captured data, and a security role to manage access to the repository and objects.

The Analyst Repository Installation Wizard lets you:
- Create a new repository.
- Upgrade an existing repository.
- Assign a repository owner.
- Assign object placement in the database.
- View feedback on the repository install actions.

Completing the Analyst Repository Installation Wizard

To install the repository, do the following:
1. On the DBArtisan toolbar, click the Capacity Analyst icon.

DBArtisan opens Capacity Analyst. Capacity Analyst detects that no repository is present and opens the Analyst Repository Installation Wizard.

2. Use the following table as a guide to understanding and setting options in the Wizard:

<table>
<thead>
<tr>
<th>Panel</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Create a new repository</td>
<td>Lets you create a new repository under a new schema.</td>
</tr>
<tr>
<td></td>
<td>Upgrade existing repository</td>
<td>Lets you upgrade the version of a current repository. Updates the stored procedures, and adds any new columns to tables. Also lets you use a an existing repository that was created for a different Analyst. NOTE: Available only if the wizard detects the presence of an earlier version.</td>
</tr>
<tr>
<td></td>
<td>Use current login information</td>
<td>IBM DB2 ONLY: Select to use the default connectivity information as the login id/password.</td>
</tr>
<tr>
<td></td>
<td>Login Name</td>
<td>Lets you type the server administrator ID. NOTE: An administrator ID is not required after the initial repository setup.</td>
</tr>
<tr>
<td></td>
<td>Password</td>
<td>Lets you type the server administrator password.</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td><strong>Login As</strong></td>
<td>ORACLE ONLY: Lets you select one of three Oracle login modes: Default - Establishes connection with no system roles. SYSDBA - Lets you perform all DBA-related functions, like startup and shutdown. NOTE: SYSDBA is required for the SYS id when you log into a 9i instance. SYSOPER - Lets you perform many DBA-related functions, like startup and shutdown.</td>
<td></td>
</tr>
<tr>
<td><strong>Using</strong></td>
<td>MICROSOFT SQL SERVER: Lets you specify authentication type, either SQL Server Authentication or Windows Authentication.</td>
<td></td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>MICROSOFT SQL SERVER ONLY: Lets you select a database. SYBASE ASE ONLY: The following system databases are excluded from the list of potential targets for Repository installation: 'Replication' 'model' 'sybsecurity' 'sybsystemdb' 'sybsystemprocs' 'tempdb' 'dbccdb' 'sybdiag'</td>
<td></td>
</tr>
<tr>
<td><strong>Login</strong></td>
<td>MICROSOFT SQL SERVER and SYBASE ASE ONLY: Lets you select an owner. NOTE: Should have the CREATE PROCEDURE privilege on the storage device that is selected. For Oracle, the storage for tables and storage for indexes are tablespaces. The owner must have privileges for the tablespaces.</td>
<td></td>
</tr>
<tr>
<td><strong>Owner</strong></td>
<td>ORACLE ONLY: Select a new user to own the repository or click New to open the User Wizard. For details, see Users Wizard (Oracle). NOTE: Should have the CREATE PROCEDURE privilege on the storage device that is selected. For Oracle, the storage for tables and storage for indexes are tablespaces. The owner must have privileges for the tablespaces.</td>
<td></td>
</tr>
<tr>
<td><strong>Storage for tables (and its available space)</strong></td>
<td>Lets you separate the storage placement of repository tables and indexes. For Oracle, the storage for tables are tablespaces. Select from the list. Or click New to open the creation wizard.</td>
<td></td>
</tr>
<tr>
<td><strong>Storage for indexes (and its available space)</strong></td>
<td>Lets you separate the storage placement of repository tables and indexes. For Oracle, the storage for indexes are tablespaces. Select from the list. Or click New to open the creation wizard.</td>
<td></td>
</tr>
<tr>
<td><strong>Password</strong></td>
<td>Lets you specify a password for the repository owner.</td>
<td></td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>IBM DB2 ONLY: Lets you select a schema. All the tables in the repository will be created for this schema. The default value is EMBTCA.</td>
<td></td>
</tr>
<tr>
<td><strong>Tablespace for Repository Tables</strong></td>
<td>IBM DB2 ONLY: Lets you select the tablespace on which the repository tables are created.</td>
<td></td>
</tr>
<tr>
<td><strong>Tablespace for Repository Indexes</strong></td>
<td>IBM DB2 ONLY: Lets you select the tablespace on which the repository tables are created.</td>
<td></td>
</tr>
<tr>
<td><strong>New</strong></td>
<td>IBM DB2 ONLY: Click to open the Tablespace Wizard. For details, see Tablespace Wizard (DB2 LUW).</td>
<td></td>
</tr>
</tbody>
</table>
Capacity Analyst Repository Installation

3. Repository Login
   Displays repository login

Execution Log
   Displays installation log.

Execution Errors
   Displays any errors if they occur.

Finish
   Click to complete the installation. Capacity Analyst installs the necessary files and displays the installation process. When the installation finishes, it displays a finished message. Click Finish to open the Capacity Analyst tab. If the installation fails, Capacity Analyst lets you stop the repository installation. Capacity Analyst deletes the objects that it created.

3. When ready, click Install.
   Capacity Analyst creates the repository. Capacity Analyst prompts you to grant other user accounts the privilege of using Capacity Analyst.

4. Select a basic security role:
   - Administrator – Users granted this privilege can create, edit, remove, and view capacity collection information.
   - User - Users granted this privilege can only view capacity collection information.

   **Tip:** You can easily grant or remove users from these roles at repository installation time or afterwards. For details, see Managing Repository Security.
Uninstalling Capacity Analyst Repository

The Capacity Analyst Repository Uninstall Wizard reverses the process completed by the Analyst Repository Installation Wizard.

Completing the Capacity Analyst Repository Uninstall Wizard

1. In the DBArtisan Datasource Navigator/Explorer, connect to a datasource that has repository installed.
2. On the Analyst toolbar, click the Capacity Analyst button.
3. On the Capacity Collection Editor toolbar, select Command, Repo Management, and then Uninstall Analyst Repo.

Capacity Analyst opens the Capacity Analyst Repository Uninstall Wizard.

4. Complete the wizard panels.
5. Click Finish.
Managing Repository Security

The **Manage Repository Security** dialog lets you manage repository security.

The table below describes the options and functionality on the **Manage Repository Security** dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Grant</td>
<td>Click to grant privileges to target user.</td>
</tr>
<tr>
<td>Revoke</td>
<td>Click to revoke privileges from target user.</td>
</tr>
</tbody>
</table>

**Completing the Manage Repository Security Dialog Box**

1. In the DBArtisan Datasource Navigator/Explorer, connect to a datasource that has repository installed.
2. On the Analyst toolbar, click the Capacity Analyst button.
3. On the Capacity Collection Editor toolbar, select Command, Repo Management, and then Manage Analyst Repo.

Capacity Analyst opens the **Manage Repository Security** dialog. The **Manage Repository Security** dialog lets you manage security for the Capacity Analyst.

4. To grant privileges, select the target user, and then click Grant.

Capacity Analyst opens the **Grant Privilege(s) To** dialog. The **Grant Privilege(s) To** dialog lets you select or clear the check boxes corresponding to the target privileges.

5. To revoke privileges, select the target user, and then click Revoke.

Capacity Analyst opens the **Revoke Privilege(s) From** dialog. The **Revoke Privilege(s) From** dialog lets you select or clear the check boxes corresponding to the target privileges.

6. Click OK.
Repository Information

The Repository Information dialog displays a tree view to present the information about the repository. The table below describes the standard nodes all datasource platforms:

<table>
<thead>
<tr>
<th>Node</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository Owner</td>
<td>Displays the login name of the repository owner.</td>
</tr>
<tr>
<td>Object Placement</td>
<td>Displays the database (for SQL Server and Sybase ASE), tablespace (for Oracle), placement for tables and indexes (filegroup name - SQL Server, segment name - Sybase ASE, tablespace - Oracle and DB2).</td>
</tr>
<tr>
<td>Repository Version</td>
<td>Schema and logic version for the tables/indexes and procedures respectively.</td>
</tr>
</tbody>
</table>

Microsoft SQL Server

The Repository Information dialog displays the following information for Microsoft SQL Server:

- Repository owner
- Repository version
- Object placement
- Database
- Filegroup name where tables are stored
- Filegroup name where indexes are stored
- Dates
- Date Created

Sybase ASE

The Repository Information dialog displays the following information for Sybase ASE:

- Repository owner
- Repository version
- Object placement
- Database
- Segment name where tables are stored
- Segment name where indexes are stored.
Repository Information

- Dates
- Date Created

**Oracle**

The **Repository Information** dialog displays the following information for Oracle:

- Repository owner
- Repository version
- Object placement
- Tablespace name where indexes and tables are stored
- Dates
- Date Created
- Date Updated

**IBM DB2**

The **Repository Information** dialog displays the following information for IBM DB2:

- Repository schema
- Repository owner
- Repository version
- Object placement
- Tablespace name where indexes and tables are stored
- Dates
- Date Created

**Completing the Repository Information Dialog Box**

1. In the DBArtisan Datasource Navigator/Explorer, connect to a datasource that has repository installed.
2. On the Analyst toolbar, click the Capacity Analyst button.
3. On the Capacity Collection Editor toolbar, select Command, Repo Management, and then Manage Analyst Repo.

Capacity Analyst opens the **Repository Information** dialog.

4. To save repository information as a report, click Save.

Capacity Analyst opens the **Save Grid** dialog.

5. In Save In, select the location for the repository file.
6. In File Name, type the file name.
7. In Save as Type, select a file type.
8. Click Save.

Capacity Analyst generates the report and returns to the Repository Information dialog.
9. Click OK.

Capacity Analyst closes the Repository Information dialog.
Capacity Analyst Tutorial

Embarcadero Capacity Analyst offers intelligent insight into the past, current, and future inner-workings of a database. By collecting historical database and performance metrics at user-defined intervals, Capacity Analyst provides historical trend analysis along with smart forecasting abilities that let you plan for the future needs of key databases. Capacity Analyst runs inside the Embarcadero DBArtisan console so you can perform all your database administration and analysis in one place.

Embarcadero Capacity Analyst lets you analyze current trends in your database storage and systems performance and helps you understand when corrective action is necessary. Capacity Analyst also helps you forecast the future needs of the your database so that your key systems can continue to meet the growing needs of its users.

Topics

- [About this Capacity Analyst Tutorial](#)
- [Session 1: Creating and Scheduling a Collection](#)
- [Session 2: Using Analysis and Reporting Tools](#)
About this Capacity Analyst Tutorial

This short tutorial helps you get started with Embarcadero Capacity Analyst. After you complete this exercise, you will have the foundation you need to explore the many features and benefits of Capacity Analyst. You will learn how to set up Capacity Analyst and become familiar with creating and scheduling statistical collections. You will also understand how to analyze database trends and perform future forecasts of your database’s needs.

Summary of the Tasks in this Tutorial

The main categories of Capacity Analyst activities are:

- **Creating and editing collections** - a collection is basically a specified set of metrics. Capacity Analyst lets you use a wizard to create collections, specifying DBMS-specific metrics as content. You can edit and clone collections as well.

- **Executing collections** - based on counters, timers, and statistics packages available from the DBMS you are working against, collections store calculated totals. Executing a collection updates the totals in the collection. Depending on your needs, you can execute collections in an ad hoc fashion or you can schedule collections to be executed at regular intervals.

- **Analysis and reporting** - Capacity Analyst provides prepackaged reports and a visual analysis tool.

This tutorial walks you through a sample of these activities. You will create a collection with a small variety of metrics, schedule the collection to be updated each hour, and use the analysis and reporting tools.

Choosing an Appropriate Database for the Tutorial Exercises

The full power of the analysis and reporting tools can only be realized if you work through the exercises against an active database. For best results, use an active test bed or a production system.

Rationale for a Two-part Tutorial

While a collection stores historical statistics, totals cannot reflect database activities that occurred before the collection was created. In order to view meaningful analysis and reports, enough time must pass to allow a bare minimum of database activity. With that in mind, this tutorial is presented in two parts:

- **Session 1: Creating and Scheduling a Collection**
- **Session 2: Using Analysis and Reporting Tools**
After completing the exercises in session 1, you should wait minimally four hours before starting the second session. This should allow sufficient database activity to allow for meaningful analysis.
Session 1: Creating and Scheduling a Collection

In Session 1, you will first ensure that you are properly set up to evaluate the Capacity Analyst. Subsequently, you will run the Capacity Analyst, build a small statistics collection, and ensure that it is updated on an hourly basis.

Getting Started with Capacity Analyst (Optional)

The following topics prepare you for first use of the Capacity Analyst:

- Downloading and Installing DBArtisan
- Starting DBArtisan and Connecting to a Datasource
- Installing the Capacity Analyst Repository

When you have performed these tasks, or if you have already performed them, you can proceed to Creating and Scheduling a Capacity Collection Using Capacity Analyst.

Downloading and Installing DBArtisan

You can obtain the latest version of Capacity Analyst by downloading the DBArtisan software from the Embarcadero Web site at http://www.embarcadero.com. Capacity Analyst runs fully-contained within DBArtisan so you will need the DBArtisan product to use Capacity Analyst.

To download and install DBArtisan

1. Locate the download area of the Web site and follow the steps indicated.
2. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for the duration of the trial period. After that time, a permanent license is needed.

Starting DBArtisan and Connecting to a Datasource

After installing DBArtisan, you must set up datasources to establish reusable connections to your database servers. For now, you can establish a single connection to the database/server you will use to evaluate Capacity Analyst. DBArtisan can detect and let you register any datasource in your network.

To connect to a database/server

1. Start DBArtisan. For a default installation, Start > Programs > Embarcadero DBArtisanversion number > DBArtisan (where version number corresponds to the version of DBArtisan that you downloaded).
2. On the **Datasource** menu, select **Discover Datasources**.

The **Discover Datasources** dialog opens. After searching your network it lists all datasources to which you can connect.

3. Select the check box corresponding to the target datasource and click **Register**.

The datasource is added to the Datasource Navigator/Explorer, under the relevant DBMS folder. For example:

![Datasource Navigator/Explorer](image)

4. Right-click the datasource and select **Connect** from the context menu.

A login dialog opens.

5. Provide valid user name and password credentials and click **OK**.

### Installing the Capacity Analyst Repository

Capacity Analyst makes use of a repository to store historical statistics about your database. A repository is required for each database/server that you use with Capacity Analyst.

**To install a repository on the datasource you connected to**

1. From the **Analyst** menu, select **Capacity Analyst**.

OR

2. On the Analyst Series toolbar, click the Capacity Analyst button.

DBArtisan opens Capacity Analyst. Capacity Analyst detects that no repository is present and opens the Analyst Repository Installation Wizard.

Depending on the type of DBMS type of the datasource you connected to, specific options will differ. In general, the Wizard prompts for login/password credentials, as well as server, database, and storage details.

3. Provide the information that the Wizard prompts you for and when complete, click the **Install** button and provide additional information when prompted.
Creating and Scheduling a Capacity Collection Using Capacity Analyst

Creating a New Capacity Collection Using Capacity Analyst

To get started collecting information for your database, you first need to create a new collection. A collection is essentially a set of related metrics or statistics that you want to report on. As you begin to make use of Capacity Analyst, you will develop a strategy for metrics you will store in each collection. For the purposes of this tutorial, you can build an arbitrary set of statistics into a collection.

You create a collection using the Capacity Collection Wizard.

To open the Capacity Collection Wizard

1. On the Capacity Analyst toolbar, click the New Collection Wizard button.

Capacity Analyst opens the Capacity Collection Wizard.
The first panel is devoted to naming your capacity collection and specifying various collection properties like descriptions and optional job completion notifications.

To complete the Wizard

1. Provide the information in the fields provided and click the Next button to continue.

Capacity Analyst opens the Selection Types panel of the Capacity Collection Wizard. The second panel asks you what type of information you would like to collect for your database. While this panel prompts you to choose general categories, subsequent panels will let you provide more specific information about the choices you make here.

The specific options differ according to the type of DBMS datasource you are connected to, but in general the categories are:

- **Storage structures** - Depending on the DBMS you are working with, your analysis and reports can contain space and usage statistics on items such as databases and database devices, logs and backup space, partitions, tablespaces, filegroups, and files.

- **DB objects** - Your analysis and reports can contain space and usage statistics on tables, indexes, and for some supported DBMS types, other database objects.
Performance-based statistics - if available for the DBMS you are connected to, this lets you use product-specific performance-based statistic packages.

Wait events - if available for the DBMS you are connected to, this lets you work with wait-based event information provided by the DBMS.

2. For the purposes of this tutorial, select all options on the panel and then click Next.

The next set of panels let you select specific details. Each panel corresponds to one of the options you chose on the Selection Types panel.

Most panels offer categories that let you drill down by expanding the category to expose specific options. You can then select specific options and move them from the Available list to the Selected list and then click Next to move to the next panel.

3. Complete all panels up until the Statistics tab is displayed.

Tip: Since table and index statistics are supported for all DBMS, as an aid in subsequent sessions, select a variety of indexes and tables on the DB Objects panel.

The Statistics tab prompts you to update the statistics you chose. In order to use the analysis tools offered by Capacity Analyst, you must execute the collection. This performs calculations and rollups on the metrics in the collection, letting you produce up-to-date reports and charts.

4. Look over the options available on the Statistics panel, enable statistics update and select one or more update options, and then click Next.

The AutoPurge panel is displayed. It offers the option to delete older data, each time that you execute a collection.

5. Enable AutoPurge and click the Finish button.

Scheduling a Collection in Capacity Analyst

Immediately after your collection has been saved to the repository, Capacity Analyst prompts you if you would like to schedule the collection to run at specified intervals. It is not necessary that you schedule your collection to actually collect statistics in the repository. You can execute a collection in an ad-hoc manner at any time through the Capacity Collection Manager.

Depending on your requirements however, scheduling a collection may be the preferred route. For example, if you want to run packaged reports on a scheduled basis, scheduling collection of your collections will ensure up-to-date statistics in your scheduled reports.

For the purposes of this tutorial, you want the statistics in your collection updated every hour.

To schedule updates for your new collection
1. Select Yes when asked if you would like to schedule your new collection

The Microsoft Task Manager scheduler opens.

2. Click Advanced to open the Advanced Schedule Options dialog.

3. Select Repeat task, specify that the task is to be repeated every hour, ensure that the task is repeated until a time at least four hours from now, and click OK to close the Advanced Schedule Options dialog.

4. Click OK to schedule your collection and dismiss the dialog.

Tip: You can add, edit, or remove any schedule for any collection at a later time by using the management functions supplied in the Capacity Collection Manager interface.

Reviewing Other Collection Management Functions

While you have completed all required tasks for Session 1, it is worthwhile looking at some of the options Capacity Analyst offers in creating and updating collections. Later, as you develop a strategy for setting up the collections for your enterprise, you will use additional Capacity Analyst features in managing your collections. With respect to maintaining your collections you have the following options:

**Editing collections**

After creating a collection, you can modify general settings and the AutoPurge option. Since a collection stores totals and rolled up statistics that can be compromised, you cannot modify your choice of statistics or the objects you generate those statistics against.

**Cloning collections**

Cloning lets you create a collection based on an existing collection and modify the metrics used and options specified in the original.

**Deleting collections**

If you no longer have use for a collection or you are going to replace it, you can delete that collection.

Similarly, when you created your collection, you selected the option to update your statistics on an hourly basis. In some cases, you may require ad hoc reports or analysis. If so, you can update your collection manually.

To manually update a collection

1. In the Capacity Collection Manager, select a collection.

2. On the Capacity Analyst toolbar, click the Execute button.

Depending on the volume of statistics you specified when creating the collection, this may take a few seconds. When complete the Last Run field will reflect the update.

There are other functions contained inside the Capacity Collection Manager, however those described above are likely the ones you will use the most often when managing your capacity collections. You will gain experience using these features as you learn more about Capacity Analyst.
After several hourly updates of the statistics in the collection you created in Session 1, you are ready to start using the analysis tools. In Session 2, you will experiment with the Collection Analysis Viewer and generate one of the Capacity Analyst predefined reports.

Performing Trend Analysis Using Capacity Analyst

The Collection Analysis Viewer presents selected statistics in a graphical format and lets you view historical trends and extrapolate that data into the future.

To open the Collection Analysis Viewer, do the following:

1. Start DBArtisan again, and connect to the datasource you created earlier. If you need help, refer to Starting DBArtisan and Connecting to a Datasource.

2. On the Analyst menu, select Capacity Analyst.

3. Select the Capacity Collection that you recently created.

4. On the Capacity Analyst toolbar, click the Collection Analysis Viewer button.
Choosing the Charted Metrics You Want To View

The first time that you open the Collection Analysis Viewer, it prompts you select the metrics you want to work with. You specify the metrics using the displayed Capacity Metric dialog. For example:

To specify the metrics that are to appear in the analysis

1. From the Aggregation dropdown, select an aggregation type: Average, Maximum, or Minimum.

2. From the Type dropdown, select the type of metric you want to add, such as a table or index.

Note: Certain Metric types allow you to further qualify using the Owner and Database dropdowns.

3. From the Available Object of Type list, choose a specific object or statistics type.

The Metrics list is updated with the metrics available for the Type and Available Objects of Type selections you made.

4. Select a metric from the Metrics list and click Add.

Capacity Analyst adds the metric to the Current Metrics list.

5. To add additional metrics, repeats Step 1 through Step 4. Keep in mind that the Collection Analysis View will calibrate its chart according to the metric with the largest value. If you are going to add multiple metrics, choose metrics that you expect will have similar ranges.

6. When finished adding metrics for the graphical portion of your analysis, click OK.
Viewing Trends in Capacity Analyst

When you finish adding metrics to the Collection Analysis Viewer, Capacity Analyst presents the data in graphical and grid form in the Collection Analysis Viewer. Your first step should be to ensure that the displayed timescale reflects the fact that you have been updating metrics for a matter of hours. You do this using the controls in the Capacity Metric Attributes area.

To optimize viewing of the metrics in your collection

1. From the Metric Time Scale dropdown, choose Hours.
2. In the Last box, enter the number of hours since you scheduled your collection for hourly updates.

Having only statistics that cover a matter of hours, your viewing options are currently somewhat restrictive. However, during a later session you may want to experiment with the following viewing options:

- By default, the No Trend Analysis option is selected. This option shows historical data only. If you want statistics extrapolated into the future, you can use the Trend to Date or Trend to Value options to help you predict potential problems.
- You are currently using the Auto Period. It lets you quickly select an interval from the current day or the last statistics update. The Manual option lets you to have more granular control over the exact dates/times that Capacity Analyst uses to plot the data.
- To display the actual data values, position the pointer over the trend lines in the graph. Pop up values display the exact points on the chart.
- Each metric’s statistic displays in the Analysis viewer’s bottom grid with the high, low, and average value for the time period being shown for each metric.
- After your data has been displayed, you can continue to add or remove metrics from the Collection Analysis Viewer by using the Add or Remove toolbar buttons, and perform other functions using the various options available on the Collection Analysis viewer.

3. When ready to proceed to the next exercise, on the Capacity Analyst toolbar click the Close the Active Tab button.
Using Capacity Analyst Predefined Reports

An alternative forecasting method is through use of predefined Analysis reports. Capacity Analyst provides reports on growth trends of devices, databases, tables, rows, and other objects, as well as reports on fragmentation details and failure prediction. Like the COllection Analysis View, the reports show historical data and can be configured to extrapolate to a future date.

To generate a report on the fastest growing database objects

1. Ensure that the collection you created is selected.
2. Click the Report button.

The Capacity Analyst opens the Select Report Type dialog.

3. To create a pre-defined trend analysis report, select Analysis Report and click OK.

4. Accept the default to create a New Analysis Report.
5. Click Next.
6. From the report drop down list, select ‘N” Fastest Growing Objects. Note that there are many other reports available.
7. Accept the default Auto Entry time period of 1 day.
8. Accept the Day default rollup.
9. Specify the future date you want Capacity Analyst to use for its future ‘stop’ date.
10. Click Next.
11. Specify what databases/objects to include in the report.
12. Click Next.
13. Specify a Report File Name and a Report Title.
14. Click Execute.

Capacity Analyst opens the report in a new tab and stores an HTML-based version of the report in the location you specified in the Report File Name field.

The HTML report can be viewed in any web browser so you can build internal web sites of your forecasts for all interested parties, including project leads, and operation managers.
Using Capacity Analyst

The general categories of tasks performed using the Capacity Analyst are:

- **Creating and Editing Collections** - Each collection stores a set of statistics. How you set up your collections will depend on your own reporting and monitoring requirements. Capacity Analyst lets you choose the statistics in your collections and control options such as automatic purging and archiving of data.

- **Updating Statistics in Collections for use in Reports and Charts** - In order to produce up-to-date reports and charts, the rolled up data in collections must be updated. Capacity Analyst lets you update your collections manually or schedule regular, automated updates.

- **Viewing Charts and Reports on Collections** - The charts and reports available from the Capacity Analyst let you view trends and help you make forecasts regarding growth of your databases. The Collection Analysis Viewer lets you view graphical representation of the metrics in a collection as a function of time. Standard reports provide information on growth trends for devices, databases, tables, rows, and other objects, as well as fragmentation details and failure prediction.
Creating and Editing Collections

Typically, how you set up collections will be dictated by your own requirements. If your enterprise has several applications for example, each using multiple databases, you might be interested in viewing graphs and reports on an application-by-application basis, with each collection comprising statistics for several databases. At a lower level, you may be interested in viewing statistics on collections of table or indexes.

Similarly, how you set up collections can also be impacted by Capacity Analyst functionality. For example, a collection option lets you schedule statistics update at specified intervals. If your requirements include reports with different intervals, hourly as opposed to weekly for example, you could set up your collections accordingly. Or since the Collection Analysis Viewer calibrates a graph to the range of the highest valued statistic displayed, you might group statistics with similar expected values.

In short, you should consider all functionality available in Capacity Analyst before deciding on a collection setup. For details see Content and Options in a Collection and Viewing Charts and Reports on Collections.

The following topics provide details on creating and editing Capacity Analyst collections:

- Creating a New Collection
- Editing a Capacity Collection
- Cloning a Collection
- Deleting a Collection

Content and Options in a Collection

The reports and analysis you work with using Capacity Analyst include such statistics as space usage and access count details on database objects, databases, files and other storage mechanisms. They can also include performance-based and wait based statistics. The specific content and options available depend on the DBMS that DBArtisan is working with. The following topics provide summaries of available options and content on a product-by-product basis:

- IBM DB2 for Windows, Unix, and Linux Capacity Collection Content and Options
- Microsoft SQL Server Capacity Collection Content and Options
- Oracle Capacity Collection Content and Options
- Sybase ASE Capacity Collection Content and Options
IBM DB2 for Windows, Unix, and Linux Capacity Collection Content and Options

When creating or editing a Capacity Analyst collection, you specify the statistics you want in that collection and specify additional notification and update options. The table below summarizes the available statistics and options on the tabs/panels of collection wizards and editors for this DBMS.

<table>
<thead>
<tr>
<th>Content/Option Category</th>
<th>Editor Tab or Wizard panel</th>
<th>Description or specific DBMS feature support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identification/Notification</td>
<td>General</td>
<td>Lets you provide a name and description for the collection and optionally, provide an email address or net send name for notifications.</td>
</tr>
<tr>
<td>Types of statistics collected</td>
<td>Selection Types</td>
<td>Lets you select the types of content and options you want to include in the collection. You provide specifics in subsequent panels/tabs.</td>
</tr>
<tr>
<td>Database/storage structure space statistics</td>
<td>Storage Structures</td>
<td>A DB2 capacity collection can contain usage statistics on database (partition) space, DMS tablespace space, and SMS tablespace space.</td>
</tr>
<tr>
<td>Specific database object types for which to collect statistics</td>
<td>DB Objects</td>
<td>A DB2 capacity collection can contain usage statistics on indexes and tables.</td>
</tr>
<tr>
<td>Update and rollup options</td>
<td>Statistics</td>
<td>A DB2 capacity collection offers the option to update statistics with additional specific choices for tables (distribution and column options), indexes (collection of extended and sample statistics), and access options (allowing read/write access during collection).</td>
</tr>
<tr>
<td>Automatic purging of old data</td>
<td>AutoPurge</td>
<td>Offers the option to automatically purge data older than a specified age, each time the collection is updated.</td>
</tr>
</tbody>
</table>

For information on how to create and edit collections, see:
- Creating a New Collection
- Editing a Capacity Collection
- Cloning a Collection

Microsoft SQL Server Capacity Collection Content and Options

When creating or editing a Capacity Analyst collection, you specify the statistics you want in that collection and specify additional notification and update options. The table
Creating and Editing Collections

below summarizes the available statistics and options on the tabs/panels of collection wizards and editors for this DBMS.

<table>
<thead>
<tr>
<th>Content/Option Category</th>
<th>Editor Tab or Wizard panel</th>
<th>Description or specific DBMS feature support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identification/Notification</td>
<td>General</td>
<td>Lets you provide a name and description for the collection and optionally, provide an email address or net send name for notifications.</td>

<td>DB Objects</td>
<td>An SQL Server capacity collection can contain usage and size statistics on indexes and tables.</td>
</tr>
<tr>
<td>Wait-event-based statistics</td>
<td>Wait Events</td>
<td>An SQL Server capacity collection can contain statistics on SQL Server Wait Types</td>
</tr>
<tr>
<td>Performance-based statistics</td>
<td>Performance Statistics</td>
<td>Provides statistics in the following performance counter categories: Access Methods, Buffer Manager, Buffer Partition, Databases, General Statistics, Latches, Locks, Memory Manager, SQL Statistics</td>
</tr>
<tr>
<td>Update and rollup options</td>
<td>Statistics</td>
<td>Provides the option to update statistics with additional options to specify a scan range, specify index or columns update, and recompute statistics</td>
</tr>
<tr>
<td>Automatic purging of old data</td>
<td>AutoPurge</td>
<td>Offers the option to automatically purge data older than a specified age, each time the collection is updated.</td>
</tr>
</tbody>
</table>

For information on how to create and edit collections, see:

- Creating a New Collection
- Editing a Capacity Collection
- Cloning a Collection

**Oracle Capacity Collection Content and Options**

When creating or editing a Capacity Analyst collection, you specify the statistics you want in that collection and specify additional notification and update options. The table
below summarizes the available statistics and options on the tabs/panels of collection wizards and editors for this DBMS.

<table>
<thead>
<tr>
<th>Content/Option Category</th>
<th>Editor Tab or Wizard panel</th>
<th>Description or specific DBMS feature support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identification/Notification</td>
<td>General</td>
<td>Lets you provide a name and description for the collection and optionally, provide an email address or net send name for notifications.</td>
</tr>
<tr>
<td>Types of statistics collected</td>
<td>Selection Types</td>
<td>Lets you select the types of content and options you want to include in the collection. You provide specifics in subsequent panels/tabs.</td>
</tr>
<tr>
<td>Database/storage structure space statistics</td>
<td>Storage Structures</td>
<td>All tablespace, all non-temporary tablespaces, or select specific tablespaces</td>
</tr>
<tr>
<td>Specific database object types for which to collect statistics</td>
<td>DB Objects</td>
<td>Lets you include statistics on clusters, indexes, index partitions, rollback segments, tables, and table partitions.</td>
</tr>
<tr>
<td>Wait-event-based statistics</td>
<td>Wait Events</td>
<td>Lets you include statistics based on Oracle Wait Events.</td>
</tr>
<tr>
<td>Performance-based statistics</td>
<td>Global Stats</td>
<td>Lets you include Global Database Statistics.</td>
</tr>
<tr>
<td>Update and rollup options</td>
<td>Statistics</td>
<td>Offers the option to update statistics with additional options to compute or estimate statistics.</td>
</tr>
<tr>
<td>Automatic purging of old data</td>
<td>AutoPurge</td>
<td>Offers the option to automatically purge data older than a specified age, each time the collection is updated.</td>
</tr>
</tbody>
</table>

For information on how to create and edit collections, see:
- Creating a New Collection
- Editing a Capacity Collection
- Cloning a Collection

**Sybase ASE Capacity Collection Content and Options**

When creating or editing a Capacity Analyst collection, you specify the statistics you want in that collection and specify additional notification and update options. The table below summarizes the available statistics and options on the tabs/panels of collection wizards and editors for this DBMS.
### Creating and Editing Collections

<table>
<thead>
<tr>
<th>Content/Option Category</th>
<th>Editor Tab or Wizard panel</th>
<th>Description or specific DBMS feature support</th>

For information on how to create and edit collections, see:

- [Creating a New Collection](#)
- [Editing a Capacity Collection](#)
- [Cloning a Collection](#)

### Creating a New Collection

Capacity Analyst has a Wizard that walks you through specifying the statistics and options in a collection. Before creating a new collection, you should be familiar with the material in [Content and Options in a Collection](#).

**To create a new collection**

1. Open the Capacity Analyst. See [Opening the Capacity Analyst](#).
2. On the Capacity Analyst toolbar click the [New Collection Wizard](#) button.
Creating and Editing Collections

The Capacity Collection Wizard opens.

3. Provide the information required on each panel of the Wizard. For more information on these options, see the relevant DBMS-specific topic under Content and Options in a Collection.

4. When done click Finish.

Capacity Analyst offers the option to schedule updates for the statistics in this collection.

5. If you decide to schedule statistics updates, use the Windows Task Scheduler to provide update details.

Capacity Analyst adds the new collection to the Capacity Collection list.

See the following tasks for information on tasks you can perform after creating a collection:

- Editing a Capacity Collection
- Updating Statistics in Collections for use in Reports and Charts
- Viewing Charts and Reports on Collections

Editing a Capacity Collection

Because a collection stores rolled up statistics, all gathered and calculated over a specific interval, editing statistics in a collection could corrupt the data in a collection. Therefore, you cannot modify the statistics in a collection or the devices, databases or database objects that statistics are gathered against. You can only modify the basic identifiers for the collection and the refresh and autopurge options.

To edit an existing collection

1. Open the Capacity Analyst. See Opening the Capacity Analyst.

2. Select the collection to be edited and then on the Capacity Analyst toolbar click the Open Collection button.

3. On the General tab, edit the name, description, email address, or net send name.

4. On the Statistics tab, enable or disable update of statistics when you save your changes.

5. On the AutoPurge tab, enable or disable autopurge of older data when you save your changes.

6. Click OK.
Creating and Editing Collections

Cloning a Collection

The Capacity Analyst lets you create a new collection from an existing collection. This lets you build a new collection starting from properties defined in the existing collection.

To make a copy of an existing collection

1. Open the Capacity Analyst. See Opening the Capacity Analyst.
2. Select the collection to be cloned and then on the Capacity Analyst toolbar click the Clone Collection button.

Capacity Analyst opens the Capacity Analyst Collection Wizard. With the exception of the collection name, all statistics and options specified for the new collection are identical to those for the existing collection.

3. Minimally, provide a name for the new collection. Complete each panel of the wizard, changing settings as required. For more information on these options, see the relevant DBMS-specific topic under Content and Options in a Collection.
4. When done click Finish.

Capacity Analyst offers the option to schedule updates for the statistics in this collection.

5. If you decide to schedule statistics updates, use the Windows Task Scheduler to provide update details.

Capacity Analyst adds the new collection to the Capacity Collection list.

See the following tasks for information on tasks you can perform after cloning a collection:

- Editing a Capacity Collection
- Updating Statistics in Collections for use in Reports and Charts
- Viewing Charts and Reports on Collections

Deleting a Collection

If you no longer use the reports or analysis associated with a collection, Capacity Analyst lets you delete the collection.

To delete a collection

1. Open the Capacity Analyst. See Opening the Capacity Analyst.
2. Select a collection and then on the Capacity Analyst toolbar click the Delete button.
Updating Statistics in Collections for use in Reports and Charts

Once you have installed and set up Capacity Analyst on a server, raw statistics are gathered and stored in the repository on that server. In order to view up-to-date charts and reports, you must execute a collection. Executing the collection calculates totals and performs all rollups for that collection in preparation for reporting.

There are two methods of updating statistics in a collection:
- **Manually Updating Collections**, useful prior to running an ad hoc report
- **Scheduling Updates of Collections** to run regularly, useful when reporting is performed on a regular basis

**Manually Updating Collections**

You can manually execute a statistics collection. This calculates totals and statistical indicators such as averages used for reporting for that collection.

**To manually execute a collection**

1. Open the Capacity Analyst. See Opening the Capacity Analyst.
2. Select a collection and then on the Capacity Analyst toolbar click the **Execute** button.

When complete, the **Last Run** field reflects the time that the collection was updated.

After executing a collection, you can run reports or view charts for that collection, that are up-to-date as of the time that you executed the collection. For details, see Viewing Charts and Reports on Collections.

**Scheduling Updates of Collections**

If you run reports or want to regularly archive statistics for intervals, you can schedule execution of statistics collections. This updates the totals, rollups, and statistical indicators such as averages, on a regular basis. You can schedule collection updates to occur regularly such as daily weekly, or monthly, or tie execution to events such as system startup, logon, or during idle time.

The following topics provide details on the scheduling tasks you can perform against a collection:
Creating an Update Collection Schedule

You can create an update collection schedule to have statistics in that collection updated at regular intervals or have updates triggered by events such as system startup or logon.

In setting up your schedule, keep the following points in mind:

- Some statistical collections depend on the underlying dynamics of the database objects being collected. For example, storage structure space metrics, table and index statistics, etc., are oftentimes best collected only once a day. Other statistics, such as wait events and global database metrics can be collected on a much more granular level (every hour, etc.)

- If you routinely stop and start your database at a certain time, you may want to ensure that your collection job is not scheduled to run during its downtime. Also realize that stopping and starting a database resets the counters used for wait events and global database metrics.

- If you use the Microsoft scheduler on your machine, remember to not turn your machine off during the times your collection is scheduled to run or the job will not run.

Tip: You can add, edit, or remove any schedule for any collection at a later time by using the management functions supplied in the Capacity Collection Manager interface.

To schedule updates for a collection

1. Open the Capacity Analyst. See Opening the Capacity Analyst.

2. Select a Capacity Collection that currently does not have an associated execution schedule.

3. Click the Schedule button.

Capacity Analyst opens the Job Scheduler.

4. Use the Job Scheduler to specify the frequency of the report or the event that triggers the update, and other details of the schedule.

5. When finished, click OK.
Updating Statistics in Collections for use in Reports and Charts

Editing an Update Collection Schedule

After creating an update schedule for a statistics collection, you can revise the schedule. You may wish to change the frequency of updates or the event which triggers an update, or more specific details of the update schedule.

To modify the update schedule for a collection

1. Open the Capacity Analyst. See Opening the Capacity Analyst.
2. Select a Capacity Collection that currently has an associated execution schedule.
3. Click the Edit Schedule button.

Capacity Analyst opens the Job Scheduler.

4. Use the Job Scheduler to change the frequency of the report or the event that triggers the update, and other details of the schedule.
5. When finished, click OK.

Deleting an Update Collection Schedule

If you no longer want statistics in a collection to be calculated on a regular basis or if you want to create a new, completely reworked schedule, you can delete the existing schedule for a collection.

To unschedule a Capacity Collection

1. Open the Capacity Analyst. See Opening the Capacity Analyst.
2. Select a Capacity Collection.
3. On the Capacity Analyst toolbar, click the Unschedule button.

Capacity Analyst unschedules the Capacity Collection.

Purging Old Data in a Collection

Policy or practicality may dictate that the metrics in your analysis and reports not include data older than a specified date. Capacity Analyst lets you manually purge data older than a specified number of months or years.

Note: In addition to manually purging old data, when creating or editing a collection, you can set up the collection to automatically purge data older than a specified date on every update. For details, see Creating and Editing Collections.
To manually purge collection data older than a specified number of months or years

1. Open the Capacity Analyst. See [Opening the Capacity Analyst](#).
2. Select a Capacity Collection.
3. On the toolbar, click the Purge button.

The **Perform Manual Data Purge** dialog opens.

4. Use the controls in the **Purge data older than** area to provide a specific number of months or years.
5. Click **Execute** and when prompted to confirm, click **Yes**.

**Topics**

- [Creating and Editing Collections](#)
- [Viewing Charts and Reports on Collections](#)
Viewing Charts and Reports on Collections

The preliminary steps in setting up Capacity Analyst are Creating and Editing Collections and Updating Statistics in Collections for use in Reports and Charts. Once your collections are defined and the statistics updated, Capacity Analyst lets you view forecasting/trends charts and reports on your collections. Key options are:

- Using the Collection Analysis Viewer - lets you view charted representations of collection metrics as a function of time.
- Working with Capacity Analyst Reports - lets you work with predefined reports that focus on growth of databases, storage mechanisms, and specific database objects, as well as failure prediction and fragmentation.

Using the Collection Analysis Viewer

The Collection Analysis Viewer lets you perform ad hoc analysis of statistics in a collection. It presents the metrics in two formats: a graphical representation that shows values over time and a tabular format that includes metrics such as average, maximum, and minimum values.

The Collection Analysis Viewer lets you:
Viewing Charts and Reports on Collections

- View historical trends for a metric and extrapolate into the future
- Compare and contrast multiple metrics
- Vary the time scale for fine-grained or coarse-grained views

The first time that you open the Collection Analysis Viewer on a particular collection, you are prompted to select the metrics you want to view for that collection. Subsequently, when using the Collection Analysis Viewer against that collection, you can add metrics to and delete metrics from the collection.

**To open the Collection Analysis Viewer on a collection**

1. Open the Capacity Analyst. See [Opening the Capacity Analyst](#).
2. Select a Capacity Collection. For more information, see [Creating and Editing Collections](#).
3. On the toolbar, click the **Collection Analysis Viewer** button.

**Note:** If this is the first time you have opened this particular collection, you are prompted to specify the statistics to display. For help with this step, see [Adding Metrics to the Collection Analysis Viewer for a Collection](#).

Capacity Analyst opens the Collection Analysis View or the selected collection.

Viewing options available when working with the Collection Analysis Viewer include:

- Using the Delete Metric button to remove a statistic from the displayed metrics for a collection
- Using the zoom buttons on the Collection Analysis Viewer toolbar to zoom in and out on the report
- Using the refresh button on the Collection Analysis Viewer toolbar to update displayed values
- Using the **Collection** dropdown to open the Collection Analysis Viewer on a different collection
- Using the **Metric Time Scale** dropdown to choose between displayed time scales of hours, days, months, or years
- Using the trending and value dropdowns to extrapolate metric values out to specified values or specific dates
- Using the **Period** controls to change the date/time range displayed
Viewing values for metrics at specific locations on the graph by floating the cursor over specific locations on the curve

Adding Metrics to the Collection Analysis Viewer for a Collection

There are two situations in which you can add metrics viewed using the Collection Analysis Viewer:

- The first time that you open the Collection Analysis Viewer for a given collection
- When you want to manually add metrics by clicking the Collection Analysis Viewer toolbar’s Add Metric button:

In both cases, Capacity Analyst opens a **Capacity Metric** dialog to let you add metrics.

For each metric you want to add to the Capacity Analyst Analysis Viewer:

1. From the **Aggregation** dropdown, select an aggregation type: **Average**, **Maximum**, or **Minimum**.
2. From the **Type** dropdown, select the type of metric you want to add.

*Note:* Certain Metric types allow you to further qualify using the **Owner** and **Database** dropdowns.

3. From the **Available Object of Type** list, choose a specific object or statistics type.

The **Metrics** list is updated with the metrics available for the **Type** and **Available Objects of Type** selections you made.
4. Select a metric from the **Metrics** list and click **Add**.

Capacity Analyst adds the metric to the **Current Metrics** list.

5. To add additional metrics, repeats Step 1 through Step 4.

6. When finished adding metrics for the Capacity Analyst Collection Analysis Viewer, click **OK**.

Capacity Analyst updates the Collection Analyst Viewer with the new metrics.

**Working with Capacity Analyst Reports**

Capacity Analyst provides two report options. For details, see the following topics:

- **Running a Capacity Collection Summary Report** - lets you view a summary of the metrics and options currently defined for a collection.
- **Running an Analysis Report** - lets you view one of several predefined reports focusing on growth trends

**Running a Capacity Collection Summary Report**

You can produce a high-level summary of the content and options associated with a collection. It includes:

- Basic identification information such as the name, associated datasource, and owner of the collection
- A listing of the options, refresh and auto-purge for example, chosen for that collection
- A summary of the types of statistics available for use in the collection
- A detailed listing of the objects for which statistics are collected

**Note:** For a detailed listing of the specific statistics and options available for the DBMS you are working with, see the DBMS-specific heading under **Content and Options in a Collection**.

**To run a Capacity Collection Summary Report**

1. Open the Capacity Analyst. See **Opening the Capacity Analyst**.
2. Select a Capacity Collection. For more information, see **Creating and Editing Collections**.
3. On the Capacity Analyst toolbar, click the Report button.

Capacity Analyst opens the **Select Report Type** dialog.

4. Select **Capacity Collection Summary Report** and click **OK**.
Capacity Analyst opens the summary report in a new tab.

**Running an Analysis Report**

Capacity Analyst lets you run a set of predefined reports against a collection. The reports and their availability by DBMS are:

- Database growth trends (Sybase ASE, SQL Server, DB2)
- Tablespace failure prediction (Oracle)
- Tablespace growth trends (DB2, Oracle)
- Device growth trends (Sybase ASE)
- Filegroup growth trends (SQL Server)
- File growth trends (SQL Server)
- Object growth trends (Sybase ASE, SQL Server, DB2, Oracle)
- Object extent trends (Sybase ASE, SQL Server)
- Object extent failure prediction
- Database backup growth trends (SQL Server)
- ‘N’ Fastest growing databases (Sybase ASE, SQL Server, DB2)
- ‘N’ Fastest growing tablespaces (Oracle)
- ‘N’ Fastest growing objects (Sybase ASE, SQL Server, DB2, Oracle)
- Table rows trend (Sybase ASE, SQL Server, DB2, Oracle)
- Table chained/migrated rows trend (Oracle)
- Table forwarded records trend (Sybase ASE, SQL Server)
- Index level trend (Oracle)
- Object fragmentation trends (Sybase ASE, SQL Server, DB2)
- Tablespace fragmentation trend (Oracle)
- Database failure prediction (Sybase ASE, SQL Server)
- DMS tablespace failure trends (Oracle)

**To run an analysis report**

1. Open the Capacity Analyst. See [Opening the Capacity Analyst](#).
2. Select a Capacity Collection. For more information, see [Creating and Editing Collections](#).
3. On the Capacity Analyst toolbar, click the Report button.
Capacity Analyst opens the **Select Report Type** dialog.

4. Select Analysis Report and click OK.

5. Use the following table as a guide to understanding the settings and options for this wizard

<table>
<thead>
<tr>
<th>Panel</th>
<th>Tasks and settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Panel 1</td>
<td>Do you wish to create a new analysis report or 'playback' a previously saved report definition?</td>
<td>As the last step in generating a report, you are offered the option to save the report definition, for the purpose of running the report again. If you have already saved report definitions, you can use this panel to enable the Previously Saved Report option and select the existing report definition. Otherwise, to run an ad hoc report or start a new report definition, you can use the New Analysis Report option.</td>
</tr>
<tr>
<td>Panel 2</td>
<td>What report would you like to create?</td>
<td>Lets you select one of the predefined report types listed above.</td>
</tr>
<tr>
<td></td>
<td>Enter the time period sample to use for the report</td>
<td>Auto Entry lets you specify a number of days, months or years while Manual Entry lets you provide specific start and end dates.</td>
</tr>
<tr>
<td></td>
<td>Enter the time rollup to use for the report.</td>
<td>Lets your report display statistics rolled up by day, month, or year.</td>
</tr>
<tr>
<td></td>
<td>Enter the date to use for forward predictions.</td>
<td>Lets you enter a future end date that the Capacity Analyst uses to forecast.</td>
</tr>
<tr>
<td></td>
<td>Select options for the report.</td>
<td>The options offered differ by the type of report you selected and the DBMS that DBArtisan is working with.</td>
</tr>
<tr>
<td>Panel 3</td>
<td>Include objects for report.</td>
<td>Expand or collapse databases or owner lists to display specific object types and use the arrow buttons to move selected objects between the Available and Selected lists.</td>
</tr>
<tr>
<td>Panel 4</td>
<td>Data will be presented in text/grid format.</td>
<td>Lets you specify file name and path where the report will be stored and provide a title for the report.</td>
</tr>
<tr>
<td></td>
<td>Save this report definition?</td>
<td>Lets you save the report definition, specifying the file name and path for the definition.</td>
</tr>
</tbody>
</table>

6. When complete, click Schedule or Execute to run the report.

When complete, the report opens in a new DBArtisan tab.

**Note:** When viewing the report in DBArtisan, you can use the toolbar’s **Refresh** button to update values displayed.
Performance Analyst

Performance Analyst is a robust client-side monitoring product that presents a complete picture of a database’s performance. Performance Analyst is a quick, lightweight tool that lets you investigate performance bottlenecks.

The table below describes the major sections of Help.

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Welcome to Performance Analyst</td>
<td>Provides information about installing, opening, and licensing Performance Analyst.</td>
</tr>
<tr>
<td>Performance Analyst Application Basics</td>
<td>Provides conceptual information about Performance Analyst’s product design and navigation.</td>
</tr>
<tr>
<td>Performance Analyst for Oracle Tutorial</td>
<td>Helps you get started with Embarcadero Performance Analyst. Provides the foundation you need to explore the many features and benefits of Performance Analyst.</td>
</tr>
<tr>
<td>Oracle Performance Analyst Statistics</td>
<td>Performance Analyst includes expert help for all supported database platforms.</td>
</tr>
<tr>
<td>Performance Analyst for Microsoft SQL Server Tutorial</td>
<td>Helps you get started with Embarcadero Performance Analyst. Provides the foundation you need to explore the many features and benefits of Performance Analyst.</td>
</tr>
<tr>
<td>Microsoft SQL Server Performance Analyst Statistics</td>
<td>Performance Analyst includes expert help for all supported database platforms.</td>
</tr>
<tr>
<td>Performance Analyst for Sybase ASE Tutorial</td>
<td>Helps you get started with Embarcadero Performance Analyst. Provides the foundation you need to explore the many features and benefits of Performance Analyst.</td>
</tr>
<tr>
<td>Sybase ASE Performance Analyst Statistics</td>
<td>Performance Analyst includes expert help for all supported database platforms</td>
</tr>
<tr>
<td>Performance Analyst for IBM DB2 for Linux, Unix and Windows Tutorial</td>
<td>Helps you get started with Embarcadero Performance Analyst. Provides the foundation you need to explore the many features and benefits of Performance Analyst.</td>
</tr>
<tr>
<td>IBM DB2 (W/U/L) Performance Analyst statistics</td>
<td>Performance Analyst includes expert help for all supported database platforms.</td>
</tr>
</tbody>
</table>
Welcome to Performance Analyst

Performance Analyst is a client-side only visual database monitor that displays current database performance data, including key performance metrics, bottleneck analysis, and user-configurable thresholds.

Running inside the Embarcadero DBArtisan console, or stand-alone in a Web browser, Performance Analyst lets you identify performance problems that threaten database availability or response times.

Supported DBMS

Embarcadero Technologies currently offers Performance Analyst for Oracle 9i - 10g. Performance Analyst does not support Oracle Clients 7.3.4, 8.1.7, and 9.2. Performance Analyst also supports Microsoft SQL Server and DB2.

Licensing Performance Analyst

Availability of this feature depends on your licensing. For more information, see Licensing.

Operating System Prerequisites

Performance Analyst requires prerequisites for performance monitoring Windows 2000/XP and UNIX and Linux. The connectivity requirements for the various servers are minimum requirements. The other requirements are optional.

Windows 2000/XP Prerequisites

Connectivity
Performance Analyst requires the following minimum conductivity prerequisites:

- Remote Registry Service should be running on the server if Performance Analyst is connecting to a remote machine. For local machine this does not matter.
- Adequate permissions to connect to the remote computer’s registry.

Other Requirements
Performance Analyst requires the following optional prerequisites:

- Diskperf should be running on the server.

Note: You can start diskperf by executing diskperf -y from the command line.

UNIX and Linux Prerequisites

Connectivity
Performance Analyst requires the following minimum conductivity prerequisites:

- Ability to connect to the server and execute commands on the server using one of the following protocols:
  - Telnet
  - SSH
  - Rlogin
- Make sure that the appropriate daemon is running on the server and that the userid used for connecting has the permission to connect using the appropriate protocol.

Commands
The table below describes the commands that the connection Userid needs to have access to, to collect performance stats. The default path for the Userid on UNIX should be setup so you can execute the commands without qualifying them with a path.
<table>
<thead>
<tr>
<th>Command Type</th>
<th>Description</th>
<th>Commands/Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>Common Commands</td>
<td>Required on all UNIX and Linux servers.</td>
<td>ps, wc, cat, grep, vmstat, uname, uptime, who, df, netstat</td>

</tr>
<tr>
<td>HP Commands</td>
<td>Required for HP</td>
<td>/etc/swapinfo sar permission to access the following: /dev/mem /dev/kmem /var/adm/syslog/syslog.log</td>
</tr>
</tbody>
</table>
Opening Performance Analyst for the First Time

For Performance Analyst to work, a platform-specific package needs to be installed by the SYS account. When Performance Analyst first starts, it checks for the presence of this package and if it has not been installed, Performance Analyst prompts you to install it. Once created, any account with access to this package can monitor databases using Performance Analyst. You do not need to install any other objects on a monitored database.

Note: You must have SYS privileges to install the required packages. After the packages are installed, anyone can use them.

To open the Performance Analyst for the first time, connect to a database through DBArtisan and then select Performance Analyst from the Analyst drop-down menu.

Subsequently, you can connect to Performance Analyst by going to Start>Programs>EmbarcaderoDBArtisan>Performance Analyst.

When you open the Performance Analyst this way, you can only review one datasource at a time, as is the case when you open Performance Analyst remotely.

Note: If you are connecting through your client machine, it will save you time and give you greater flexibility to connect to Performance Analyst through the DBArtisan console. If you connect through the console, you can open multiple Performance Analyst windows for as many datasources as you like and switch between them by clicking the target tab.

You can also open Performance Analyst in stand-alone mode from your Web client. To do this, see: Opening Performance Analyst in Stand-Alone Mode from Your Web Client

Opening Performance Analyst in Stand-alone Mode from your Web Client

The Embarcadero Performance Analyst Login dialog box lets you open Performance Analyst in stand-alone mode from a Web client. This way you can check the performance of any or all datasources that are registered through DBArtisan when you are working remotely.

To connect to the Performance Analyst when you are not using the DBArtisan console, simply go to

<installation directory>:\PAnalyst\PerfAnalyst.html

When you’ve made the connection, a login dialog opens.

If you are connecting to the Performance Analyst from your Web client, you can only see one database at a time.
Note: Keep in mind that when you connect to Performance Analyst remotely, the Auto Connect option you may have selected when you registered the target datasource in DBArtisan is not functional. You must supply a valid user ID and password to log in to Performance Analyst successfully.

Login As: is only an option when you are logging into an Oracle database. Sybase ASE, SQL Server and DB2 log in as default. The properties for the login roles are as follows:

- Default - Establishes a connection with no system roles.
- SYSDBA - Lets you perform all DBA-related functions. SYSDBA is required for the SYS id when you log into a 9i or later instance.
- SYSOPER - Lets you perform many DBA-related functions, like startup and shutdown.
Performance Analyst Application Basics

Performance Analyst displays a complete picture of a database’s performance. Performance Analyst is a quick, lightweight tool that lets you investigate performance bottlenecks.

For more information, see Product Design.

Topics

- Performance Analyst Product Design
- Performance Analyst Product Navigation
- Alarm Sound
Performance Analyst Product Design

The Performance Analyst product design includes Home Pages.

Home Pages for Oracle

Performance Analyst displays home pages of various performance categories with detailed performance data. The Performance Analyst product design includes the following home pages:

- Home View (Oracle Performance Analyst)
- Memory View (Oracle Performance Analyst)
- I/O View (Oracle Performance Analyst)
- Objects View (Oracle Performance Analyst)
- OS View (Oracle Performance Analyst)
- RAC Detail View (Oracle Performance Analyst)
- Space View (Oracle Performance Analyst)
- Users View (Oracle Performance Analyst)

Home Pages for Microsoft SQL Server

Performance Analyst displays home pages of various performance categories with detailed performance data. The Performance Analyst product design includes the following home pages:

- Home View (SQL Server Performance Analyst)
- Database View (SQL Server Performance Analyst)
- Memory View (SQL Server Performance Analyst)
- I/O View (SQL Server Performance Analyst)
- Space View (SQL Server Performance Analyst)
- Users View (SQL Server Performance Analyst)
- OS View (SQL Server Performance Analyst)

Home Pages for IBM DB2 for Linux, Unix, and Windows

Performance Analyst displays home pages of various performance categories with detailed performance data. The Performance Analyst product design includes the following home pages:

- Home View (DB2 LUW Performance Analyst)
- Cfg (Database Configuration)
Performance Analyst Product Design

- I/O
- Instance View (DB2 LUW Performance Analyst)
- Memory View (DB2 LUW Performance Analyst)
- OS View (DB2 LUW Performance Analyst)
- Space View (DB2 LUW Performance Analyst)
- Users View (DB2 LUW Performance Analyst)

Home Pages for Sybase ASE

Performance Analyst displays home pages of various performance categories with detailed performance data. The Performance Analyst product design includes the following home pages:

- Home View (Sybase ASE Performance Analyst)
- Databases (Sybase ASE Performance Analyst)
- I/O (Sybase ASE Performance Analyst)
- Memory View (Sybase ASE Performance Analyst)
- OS (Sybase ASE Performance Analyst)
- Space (Sybase ASE Performance Analyst)
- Users (Sybase ASE Performance Analyst)
Performance Analyst Product Navigation

Navigating Performance Analyst is easily accomplished through two main mechanisms:

1. The main Performance Analyst toolbar buttons open the major performance analysis views (the toolbar buttons you see are self-explanatory) within the product as well as frequently used actions like Refresh and Performance Threshold Customizations.

2. If you right-click any area within Performance Analyst, the application displays a shortcut menu that lets you easily move between any of the main Performance Analyst home pages and drill-down views. The shortcut menu also contains context sensitive options like drilling down further into a particular statistic, copying the display to a text file, and more.

For more information, see Toolbar Icons.

Toolbar Icons

Performance Analyst has several unique icons that take you directly to some functions and statistical groups that can help you see and sort through groupings of data. The functional icons you see on the Performance Analyst toolbar are as follows:

- **Top Sessions** - This takes you directly to the Top Sessions tab of the Users Detail view where you see the Top I/O, Memory, CPU, and Sessions statistics.

- **Top SQL** - Opens the Top SQL detail view and lets you move among the Summary, Criteria, SQL Details, and Recent History tabs.

- **Response Time (Oracle 10 g only)** - Oracle 10g collects response time statistics, which are displayed when you click the icon.

- **Alarms** - Goes directly to the Alarms log.

- **Threshold Maintenance** - Clicking here opens the Threshold Template Maintenance dialog. Thresholds are explained in the Using chapter.

- **Refresh** - Click this to update the stats/information on whatever page you are currently scrutinizing.

- **Options** - To open the Performance Analyst options dialog, where you can change the values for Oracle, SQL Server, Sybase ASE, or DB2 options, click this cheerful checkerboard.
Alarm Sound

- Exit: This closes Performance Analyst for the database you are reviewing. If you have multiple Performance Analysts open, clicking this does not close all Analysts.

- Maximize Window: This icon appears on each pane of a multi-pane window and lets you expand the pane of choice to fill the screen.

- Minimize Window: When you have seen enough of an expanded pane, you can bring it back to its original size by clicking this icon.

- Help: Another in this series of intuitive icons, click this to open the context-sensitive Help.

Alarm Sound

When you register an alarm in Performance Analyst, it creates a periodic alarm sound. To turn off the alarm sound, do the following:

1. Click Start, Programs, Accessories, Entertainment, and then Volume Control. Windows opens the Volume Control dialog.
2. Under Wave, select Mute.

Note: Hiding the Performance Analyst icon in the task bar does not mute the sound.
Using Performance Analyst

Performance Analyst allows you to organize performance metrics in the particular way you want to see them. You can drill-down into the many layers of database performance and also be able to locate performance issues in your database in a fast and effective manner. You can set alarm triggers and thresholds for multiple databases across several platforms.

For example, key ratios in Performance Analyst are calculated using delta statistics, which is superior to computing ratios with cumulative values. Delta statistics, which are values derived by using the before and after measures in each statistical refresh done in Performance Analyst, lets you see changes in performance metrics that would otherwise be invisible if cumulative statistics were used. This chapter tells you how to set the refresh intervals that best suit your needs.

So, this Using chapter explains how to reveal the layers of information you want to see. The platform-specific Expert Guides explain what you are seeing as they discuss individual statistics, the associated metrics, and troubleshooting suggestions:

- Oracle Performance Analyst Statistics
- Microsoft SQL Server Performance Analyst Statistics
- IBM DB2 (W/U/L) Performance Analyst statistics
- Sybase ASE Performance Analyst Statistics

Performance Analyst Tools

Performance Analyst offers tools that help you configure what you can see when you survey target databases. It’s an easy thing to set up an alarm notification for individual statistic thresholds based on parameters you designate. And, when you work through DBArtisan, you can easily correct problems if you notice something is amiss.

Performance Analyst supports the following functionalities:

- Alarm Log
- Change Graph Type
- Copy
- Details
- Explain SQL
- Manage with DBArtisan
- Options
- Response Time (ORACLE 10g ONLY)
- Save
- Thresholds
- Top Sessions
- Top SQL
**Alarm Log**

The Alarm Log displays every performance violation found in your currently monitored databases. Unlike some products that only show you alarms for a particular database, Performance Analyst gives you the option to see all alarms for each database you are monitoring in one central log so you can see every problem in a single place. And, of course, you have the ability to determine alarm levels by setting the Threshold Properties.

**To open an Alarm Log**

- Open the Performance Analyst and then scroll down to Alarms on the drop-down menu.
- Move your mouse over the Performance Analyst toolbar and click the exclamation point (you’ll see Alarms appear in a tool tip under the hand icon).

**Organizing the Alarm Log**

You can arrange the data in the Alarm Log in several ways:

**Note:** Changes you make to one Alarm Log are not enacted globally. This allows you to customize each log based on your needs database by database if you want.

- Move columns left or right to place them in an order that makes the most sense to you. Do this by dragging-and-dropping a column heading to re-place it in the target location.
- Sort column rows up and down or sideways. Right-click a column heading and select:
  - Sort Ascending: For example, you can see the alarms as they move from Critical to Cleared.
  - Sort Descending: For example, you can see the alarms as they move from Cleared to Critical.
  - Sort Multiple Columns: Lets you group multiple columns in ascending or descending order. You cannot mix and match, however. That is, you cannot sort some columns to present data in ascending order and others to present data in descending order.
  - Sort Clear: Lets you clear the relationships you created if you sorted multiple columns.

The table below describes the columns of the Alarm Log:
Alarm Log

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alarm Type</td>
<td>Displays alarm types: Cleared, Critical, Fair and Poor.</td>
</tr>
<tr>
<td>Datasource</td>
<td>Datasource where the alarm was identified.</td>
</tr>
<tr>
<td>DBMS Type</td>
<td>Datasource DBMS type.</td>
</tr>
<tr>
<td>Date/Time</td>
<td>Date/time of when the alarm was observed.</td>
</tr>
<tr>
<td>Category</td>
<td>Displays metric category: memory, I/O, space, objects, or users.</td>
</tr>
<tr>
<td>Statistic</td>
<td>Metric name.</td>
</tr>
<tr>
<td>Value</td>
<td>Value of the statistic that caused the violation.</td>
</tr>
<tr>
<td>Explanation</td>
<td>Displays a text explanation of the problem. These text explanations can be very generic in nature and just plug in certain threshold metrics, etc.</td>
</tr>
</tbody>
</table>

**Alarm Log Activities**

From within the Alarms Window, right-clicking any row gives you more opportunities to get the most out of what you see. The menu selections are:

- Applicable Page - Takes you to the row-specific Category page where you can see the problem metric and what’s happening with the surrounding statistics. For example, if you click a critical alarm in the Databases category, you connect immediately to the Databases home page.
- Options - Takes you to the Alarm Log Options dialog where you adjust some general alarm log properties and alarm filters.
- Clear List - When you select this, the alarm log is cleared of all entries.
- Help - Opens the Help discussion for the target element.
- Refresh - Refreshes the display to show you any updates.
- Copy - Places the data in the alarm log at that point in time on the Windows clipboard. From there you can paste it into a Word or Excel document.
- Save As - Lets you name and save the Alarm Log to the location of your choice as a Microsoft Excel worksheet. You can then manipulate the worksheet as you would any other.
- Print - Enables you to print the alarm log.

**Alarm Log Options Dialog Box**

The Alarm Log Options dialog is command central for how and where you display and manipulate previously configured alarms. Alarms themselves are configured in the
Threshold Properties, but this is where you arrange the particulars of the Alarm Log your databases. Keep in mind that changes you make to this dialog box are reflected globally across all platforms.

The table below describes the columns of the Alarm Log Options dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>General Properties</strong></td>
<td></td>
</tr>
<tr>
<td>Do not log alarms to the alarm log</td>
<td>When you select this option, alarms will not be saved to an alarm log. Depending on the filters you select, you will still see alarms in the alarm window.</td>
</tr>
<tr>
<td>Log alarms to the alarm log</td>
<td>This option lets you save alarms to an alarm log. You can type or browse to choose a directory where you want to save the log and you can also set the maximum alarm log size in KB.</td>
</tr>
<tr>
<td><strong>Filters</strong></td>
<td></td>
</tr>
<tr>
<td>Show alarms for only current datasource</td>
<td>When you select this option, you see only alarms for the current datasource in the alarm window. So, if you have multiple datasources open and you go from one to another, the alarm window will display only the alarms for the database you are observing at that very moment.</td>
</tr>
<tr>
<td>Show alarms for all currently modified datasources</td>
<td>This option lets you see what alarms are occurring across all databases you are connected to at the moment.</td>
</tr>
<tr>
<td>Show only active alarms</td>
<td>If you select this option, you’ll see only those alarms that are active at that moment in time. These are alarms that you decided to include as part of a threshold template.</td>
</tr>
<tr>
<td>Show only alarms where the Explanation contains the following text</td>
<td>Lets you fine-tune the alarms you see depending on what you are most interested in seeing. For example, if you are particularly interested in seeing Bottleneck alarms, type Bottlenecks. NOTE: The text search for this function is case-sensitive.</td>
</tr>
<tr>
<td>Show only alarms that are of the following severity</td>
<td>Select to display alarms that are critical, poor, fair, or cleared.</td>
</tr>
</tbody>
</table>
Changing Graph Type

When you are looking at a statistic that is displayed in graph form, you can very easily change how that data is displayed. When you choose to switch from one type to another, the changes are limited to the specific graph and its data that you are manipulating. So, for example, the same page can display a bar graph and a pie chart.

The graph types available to you are:

- Line Graph
- Area Graph
- Pie Graph
- Bar Graph
- Horizontal Bar Graph

To change the graph type

- Right-click the target graph, and from the drop-down menu, select Change Graph Type.

Copy

The Copy functionality lets you copy data in a tabular grid display into the Windows clipboard. The data can then be saved and used for later comparisons as you continue to tweak your databases’ performance.

To Copy data, do the following

1. Hover the pointer over the target section or metric, and then right-click and select Copy.

Performance Analyst copies data into the Windows clipboard.

2. Select an existing, or new, Word or Excel document where you want to Paste the data.

3. Save, or Save As, the document to the target location.
Details

The Details functionality lets you drill-down into the target metric data. Generally you are taken to the metric’s category detail page.

To see section or metric details

- Right-click in the target section or metric and select Details from the drop-down menu.

After you are taken to your destination, right-click again to see if another level of detail is available to you.

Explain SQL

Performance Analyst lets you run Explain SQL Plans from the Top SQL window. If you are seeing problem metrics, you can take steps to correct the SQL statements.

Opening the Explain SQL/Explain Plan

1. Click the SQL button on the Performance Analyst toolbar to open the Top SQL details page.

2. Click the SQL Details tab.

You can also right-click anywhere and select Navigate to...>Top SQL>SQL Details from the drop-down menus.

3. Move down the list of SQL text in the grid and the SQL text appears in the Selected SQL Text window.

4. Press the Explain SQL button to open the Explain Plan.
Manage with DBArtisan

Manage with DBArtisan opens the DBArtisan editor for the object that has been selected for editing in a grid/tabular display of data.

By moving directly to DBArtisan from Performance Analyst, you have an opportunity to fix database problems as soon as you see them. This option is not available, however, when you open the Performance Analyst from a Web client.

Performance Analyst Options Dialog Box

The Performance Analyst Options dialog box is where you can specify various refresh intervals, threshold polling, and datasource overrides among other settings. You can set or change defaults that are both global and platform-specific.

**Note:** The settings on the Global and Datasource tabs apply to all datasource platforms. The SQL Server, Sybase ASE, and DB2 tab settings are platform-specific. Some options on the platform-specific tabs may look as if they are available to you, but in reality they are not. For example, if you are connected to an Oracle datasource, changing the Monitoring Refresh interval on the Sybase tab is a hollow gesture.

To open the Performance Analyst Options dialog box

- Open the Performance Analyst and then scroll down to Options on the drop-down menu.
- Right-click in the Performance Analyst window for the target datasource and select Options.
- Move your mouse over the Performance Analyst toolbar and click the multicolored square (you’ll see Options appear in a tool tip under the hand icon).

The table below describes the tabs of the Performance Analyst Options dialog:

<table>
<thead>
<tr>
<th>Tab</th>
<th>Settings Group</th>
<th>Option/Description</th>
</tr>
</thead>
</table>
| Global   | Engine         | SQL metric refresh interval - Lets you set the time, in seconds, between collect cycles for the SQL metrics reflected in Performance Analyst. SQL metrics include all non-operating system metrics. OS metric refresh interval - Lets you set the time, in seconds, between collect cycles for all operating system-related metrics reflected in Performance Analyst. OS metrics include all metrics shown on the OS page. Threshold polling - Lets you determine which metrics, if any, you want to test against your pre-set thresholds. The possible settings for the Threshold polling box are: All Metrics - Polls all metrics Current Page Only - Polls only those metrics reflected on the currently open page in Performance Analyst Off - Turns polling off. If polling is turned off, Performance Analyst does not activate Alarms. Threshold polling interval - Lets you set the time, in seconds,
Performance Analyst Options Dialog Box

between collect cycles for threshold-related metrics. Once collected, the polled metrics are compared to the pre-set thresholds. If you select Off in the Threshold polling box, Performance Analyst does not poll these metrics, regardless of the interval. Run queries for all tabs - Lets you determine whether or not you want Performance Analyst to refresh all tabs according to the SQL metric refresh interval. If Run queries for all tabs is not checked, Performance Analyst runs queries only for the current tab.

Visual

Show alarms icon in system tray - Lets you determine whether or not you want Performance Analyst alarms to appear in the Windows System Tray on the lower right-hand side of your screen. If you select Show alarms icon in system tray, Performance Analyst places an icon in the Windows System Tray each time an alarm is raised.

Number of Historic Values in Graphs - Lets you specify the number of values in the graphs.

Datasource Operating System

OS type - Lets you select the operating system type for the current datasource. The options are: MS Windows - Select MS Windows for all supported types of Microsoft Windows Unix or Linux - Select Unix or Linux if you operating system is any flavor of Unix Host name - Lets you specify the name of the host for the current datasource, if necessary. Performance Analyst automatically fills in any detectable information, including the Host name box. Username - Lets you select a local or network username that Performance Analyst can use to connect to the datasource. If you select the Use Datasource Username and Password check box, the Username box is unavailable. Password - Lets you select a local or network password that Performance Analyst can use to connect to the datasource. If you select the Use Datasource Username and Password check box, the Password box is unavailable. Protocol - Lets you specify a protocol for communicating with datasources on Unix-based operating systems. The options are: SSH Telnet Rlogin Use Datasource Username and Password - Lets you specify whether or not you want to use the datasource username and password to connect to the datasource as opposed to a network or operating system username and password Save Username and Password - Lets you save the username and password that appear in the Username and Password boxes.

Overrides

SQL metric refresh interval - Lets you override the SQL metric refresh interval in the Global tab for the current datasource. The SQL metric refresh interval specifies the time, in seconds, between collect cycles for the SQL metrics reflected in Performance Analyst. SQL metrics include all non-operating system metrics. OS metric refresh interval - Lets you override the OS metric refresh interval in the Global tab for the current datasource. The OS metric refresh interval specifies the time, in seconds, between collect cycles for all operating system-related metrics reflected in Performance Analyst. OS metrics include all metrics shown on the OS page.

SQL Server Global Options

SQL Profiling Enabled - Performance Analyst requires some privileges that go along with SQL Server Profiler in order to return some statistics for SQL Server databases. Check SQL Profiling Enabled to ensure that Performance Analyst can collect all the necessary metrics.

New Datasource Defaults

Start SQL Profiling - Lets you set new datasources to start SQL Profiling when they are monitored by Performance Analyst. SQL Profiling refresh interval - Lets you set the default time for new datasources, in seconds,
Performance Analyst Options Dialog Box

between collect cycles for the SQL metrics that require the SQL Server Profiler.

Current Datasource Settings

Start SQL Profiling - Lets you set current datasources to start SQL Profiling when they are monitored by Performance Analyst. SQL Profiling refresh interval - Lets you set the default time for current datasources, in seconds, between collect cycles for the SQL metrics that require the SQL Server Profiler.

Sybase Global Options

Monitoring Table refresh interval - Lets you specify, in seconds, the amount of time between refreshes for the Monitoring Table. The Monitoring Table is a table installed by Performance Analyst used to store various metric-related information. The default is 15 seconds.

New Datasource Defaults

Use noclear option in sp_sysmon - Performance Analyst sessions are started with the 'sp_sysmon noclear' option, ensuring that monitor values are stored in a temporary file. If monitoring is being used by another application, those results are not impacted by the Performance Analyst session zeroing out counters. NOTE: The noclear option is available for Sybase ASE 12.5.3 and higher and 15.0.2 and higher.

Current Datasource Defaults

These settings are only available with a Performance Analyst session active against a Sybase ASE datasource. The settings only apply to current sessions. The Monitoring Table refresh interval and Use noclear option in sp_sysmon settings let you override the selections in the identically-named settings in the Global Options and New Datasource Defaults groups.

Use custom sample query - You can use this option to build a custom sampling query and check the database response time by reviewing the Sample Query Response Time graph on the Database home page.

DB2 Monitor Settings

Monitor Switches - You are able to set monitor switches ON for the current session. When check marks are visible, that means they were previously set as defaults. Check or uncheck the boxes as you wish. Monitor settings are available for Buffer Pool, Statement, Lock, Table, Sort, Unit of Work. Metrics for all checked elements are gathered in the current session. SQL Statement Cache - You can collect SQL statements on each refresh, collect SQL statement only when you are on the Top SQL pages, or choose not to collect any SQL statements. Database System Monitor Heap - The database system monitor heap size shows the current value, in pages, allocated for the database system monitor data. The amount of memory required for monitoring depends on the number of monitoring applications, switch settings, and the level of database activity. If you see frequent heap overflow errors in the output message window when monitoring DB2 through Performance Analyst, adjust the setting here. Save settings as default - Gives you the option to set the monitoring settings as a default for the current DB2 database or for the current session only.
Response Time for Oracle 10g

The Response Time functionality lets you analyze response times. You can review historical data and pinpoint who was on a database and what they were doing during a specific period of time.

To see Response Time statistics

- Right-click in the target and select Navigate to...>Response Time Analysis from the drop-down menu.
- Hover your mouse over the Performance Analyst toolbar and click the magnifying glass (you’ll see Response Time appear in a tool tip under the hand icon).

Save As...

The Save As option gives you an opportunity to save data in a tabular format in the location of your choice. What this means is that the current data will be saved to an existing or a new Microsoft Excel worksheet. You can then manipulate and compare data with all the functionality Microsoft Excel gives you.

To Save As

- Right-click anywhere on the metric or in the Alarm Log, for example, and choose Save As... from the drop-down menu.
Thresholds

Thresholds are the point that must be exceeded to begin producing a user-defined effect or result, or to elicit a response, such as an alarm. Performance Analyst provides default threshold templates for each database platform. The default template is applied unless you choose to apply a customized template. There are two methods to place thresholds on statistics in Performance Analyst:

- **Threshold Templates** - Threshold templates are logical containers used to define and deploy thresholds to datasources. You can apply many templates at a single time and apply a single threshold template to many datasources. To customize a template, use the Threshold Template Maintenance dialog. As you add or edit thresholds for a customized template, you make your changes in the Threshold Template Properties dialog. And finally, when you have customized a threshold template to your satisfaction, you Select Datasource(s) where you want the template to be applied.

- **Datasource Thresholds** - Datasource Thresholds are default or user-defined values that mark performance boundaries. You can apply Datasource Thresholds to specific statistics on a datasource. To make changes to a datasource threshold, use the Datasource Thresholds Maintenance dialog. From here, the Threshold Templates dialog gives you the opportunity to use a previously created template to override the target datasource’s user thresholds.

Whenever you make changes to a threshold, whether through the Threshold Template functions or from the Datasource Thresholds, you are presented with the Threshold Properties dialog where you can specify when, and what type of alarm you want to trigger.

Additionally, you can Copy a template.

**Threshold Properties Dialog Box**

Thresholds are the point that must be met to begin producing a user-defined effect or result, or to elicit a response, such as an alarm. The Threshold Properties dialog lets you modify properties for any threshold.

**To open the Threshold Properties dialog box**

- Choose Threshold Maintenance... from the Performance Analyst drop-down menu to open a Threshold Template Maintenance dialog box, and then click Add or Edit.

- You can also choose Datasource Thresholds... from the Performance Analyst drop-down menu to open the Datasource Thresholds Maintenance dialog, and then click Add or Edit.

The table below describes the options and functionality on the Threshold Properties dialog:
Thresholds

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statistic</td>
<td>Lets you choose the target statistic where you want to add a threshold. NOTE: If you are adding a statistic to a template or datasource threshold, use the drop-down list to find the statistic you want to add. When you select Edit for any statistic showing in the User Thresholds window, the target statistic is displayed.</td>
</tr>
<tr>
<td>Generate Alarm If</td>
<td>Lets you choose or change the target alarm condition. The seven options are: greater than, greater than or equal to, is equal to, is not equal to, less than, and less than or equal to.</td>
</tr>
<tr>
<td>Value amount</td>
<td>Lets you set or change the numerical value for the threshold. You cannot leave the value text box blank when you first add the threshold.</td>
</tr>
<tr>
<td>Severity</td>
<td>Lets you select the target severity level: Fair, Poor, or Critical.</td>
</tr>
</tbody>
</table>

Threshold Templates Dialog Box

Threshold Templates are logical containers used to define and deploy thresholds to datasources. Performance Analyst offers a default template for each platform. You can copy or customize and apply templates to your heart’s content. You cannot, however delete the default template.

To open the Threshold Templates dialog box

- Choose Datasource Thresholds... from the Performance Analyst drop-down menu to open the Datasource Thresholds Maintenance dialog, and then click Change.

The Threshold Templates dialog displays the available Threshold Templates. The table below describes the options and functionality of the Threshold Templates dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Displays the name(s) of the available platform-specific Threshold Template(s).</td>
</tr>
<tr>
<td>Description</td>
<td>Displays the description(s), if any of available Threshold Template(s).</td>
</tr>
<tr>
<td>Override Datasource’s User Thresholds</td>
<td>Lets you choose which thresholds to use on the target datasource - the thresholds in the Threshold Template or the user-defined thresholds on the target datasource. If you select the check box, Performance Analyst will override any Datasource Thresholds on the target datasource with the thresholds in the Thresholds Template.</td>
</tr>
</tbody>
</table>

Threshold Template Properties

Threshold Templates are logical containers used to define and deploy thresholds to datasources. The Threshold Template Properties dialog is where you create a custom template or where you edit an existing one.

To open the Threshold Template Properties dialog box
Choose Threshold Maintenance... from the Performance Analyst drop-down menu to open a Threshold Template Maintenance dialog, and then click Add or Edit.

The table below describes the options and functionality on the Threshold Template Properties dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Lets you name the threshold template you are creating. If you are editing a template, target template’s name appears here.</td>
</tr>
<tr>
<td>Description</td>
<td>Lets you type or review the target template’s description.</td>
</tr>
<tr>
<td>Platform</td>
<td>Offers a drop-down list of supported platforms. The selection box displays the target template’s platform, but you can use this list to see thresholds from other platforms.</td>
</tr>
<tr>
<td>Threshold/Severity/Condition/Template</td>
<td>Displays each threshold contained in each template for a given platform. Here you see the severity and condition of each template as well.</td>
</tr>
<tr>
<td>Arrow</td>
<td>Lets you select thresholds for the Threshold Template. When you click the arrow, Performance Analyst moves selected thresholds to the Threshold Template you are creating or editing.</td>
</tr>
<tr>
<td>Add</td>
<td>Use this function to add statistics to the threshold template you are creating/editing. When you click this button, Performance Analyst opens the Threshold Properties dialog.</td>
</tr>
<tr>
<td>Edit</td>
<td>Lets you edit the selected Datasource Thresholds appearing in the Current Template window. When you click this button, Performance Analyst opens the Threshold Properties dialog.</td>
</tr>
<tr>
<td>Delete</td>
<td>Lets you delete the selected Datasource Thresholds. When you click this button, Performance Analyst deletes the selected thresholds.</td>
</tr>
<tr>
<td>Save</td>
<td>Saves any changes you made in this dialog box to create the new or modified template.</td>
</tr>
</tbody>
</table>

Threshold Template Maintenance Dialog Box

Threshold Templates are logical containers used to define and deploy thresholds to datasources. The Threshold Template Maintenance dialog lets you add or edit templates, as well as configure template maintenance options. For example, you can copy the original Embarcadero Threshold template and modify it to fit your needs. You
can control which statistics are sampled for performance violations, as well as the levels of severity to report. When you are satisfied with your Template, you can save it, and then, in one action, apply it to one or more datasources, thereby immediately enforcing your performance standards.

To open the Threshold Template Maintenance dialog box

- Choose Threshold Maintenance... from the Performance Analyst drop-down menu.
- Hover your mouse over the red and green cylinder on the Performance Analyst toolbar and look for the Threshold Maintenance tool-tip.

The table below describes the options and functionality on the **Threshold Template Maintenance** dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform</td>
<td>This is a drop-down list of the platforms. The default is the platform of the datasource you connected to most recently, but you can make another selection.</td>
</tr>
<tr>
<td>Name</td>
<td>Displays the name(s) of available Threshold Template(s).</td>
</tr>
<tr>
<td>Description</td>
<td>Displays the description(s) of available Threshold Template(s). For customized templates, the description is merely a repetition of the template name unless you wrote something when you created or edited the template.</td>
</tr>
<tr>
<td>Add</td>
<td>Lets you create Threshold Templates. When you click this button, Performance Analyst opens the <strong>Threshold Template Properties</strong> dialog.</td>
</tr>
<tr>
<td>Edit</td>
<td>Lets you edit the selected Threshold Templates. When you click this button, Performance Analyst opens the <strong>Threshold Template Properties</strong> dialog.</td>
</tr>
<tr>
<td>Delete</td>
<td>Lets you delete the selected Threshold Templates.</td>
</tr>
<tr>
<td>Copy</td>
<td>Lets you create copies of the selected Threshold Template. When you click this button, Performance Analyst opens the <strong>Copy Template</strong> dialog.</td>
</tr>
<tr>
<td>Apply</td>
<td>Lets you select datasources to apply the selected Threshold Templates. When you click this button, Performance Analyst opens the <strong>Select Datasource(s)</strong> dialog.</td>
</tr>
<tr>
<td>Select/Unselect All</td>
<td>Lets you make global additions to your templates. NOTE: You cannot edit or delete Default templates.</td>
</tr>
</tbody>
</table>

**Datasource Thresholds Maintenance Dialog Box**

Datasource Thresholds are default or user-defined values that mark performance boundaries. You can apply Datasource Thresholds to specific statistics on a datasource. You can also combine Datasource Thresholds to create a template.
Performance Analyst offers the **Datasource Thresholds Maintenance** dialog to let you modify Datasource Thresholds. There are two panes in the **Datasource Thresholds Maintenance** dialog:

- **Applied Threshold Template**
- **User Thresholds**

To open the **Datasource Thresholds Maintenance** dialog box:

- Choose Datasource Thresholds... from the Performance Analyst drop-down menu.
- Right-click in any open Performance Analyst window and choose Datasource Thresholds... from the drop-down list.

The table below describes the options and functionality in the Applied Threshold Template box of the **Datasource Thresholds Maintenance** dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Displays the name of the target Threshold Template.</td>
</tr>
<tr>
<td>Description</td>
<td>Displays any description of the Threshold Template.</td>
</tr>
<tr>
<td>Change</td>
<td>Lets you view and edit all platform-specific Threshold Templates. When you click this button, Performance Analyst opens the <strong>Threshold Templates</strong> dialog.</td>
</tr>
<tr>
<td>Remove</td>
<td>Removes all thresholds in the Applied Threshold Template grid.</td>
</tr>
<tr>
<td>Block</td>
<td>Prevents that threshold statistic from being triggered in the template. It's almost as if that threshold never existed in the template. You can, however, reinstate the threshold trigger by highlighting and deleting it from the User Thresholds pane.</td>
</tr>
<tr>
<td>Override</td>
<td>Copies the threshold settings from the selected Threshold Template and applies the change to the user-defined Datasource Thresholds. Click this button if the template has the correct Severity and Threshold, but you want to modify the condition for triggering the alarm. When you create a &quot;User Threshold,&quot; you are overriding the threshold specified by applied template or you are including an additional threshold not included in the applied template. This may be useful if you have a group of individuals all monitoring the same primary statistics (and thus using the same template) but want to be able to give individual users the ability to modify/add/block a threshold used by the template, without affecting the original template.</td>
</tr>
</tbody>
</table>

The table below describes the options and functionality in the User Threshold box of the **Datasource Thresholds Maintenance** dialog:
Thresholds

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Threshold</td>
<td>Displays the statistic on which the threshold is placed.</td>
</tr>
<tr>
<td>Severity</td>
<td>Displays the severity for the threshold.</td>
</tr>
<tr>
<td>Condition</td>
<td>Displays the condition for the threshold.</td>
</tr>
<tr>
<td>Add</td>
<td>Lets you create Datasource Thresholds. When you click this button, Performance Analyst opens the Threshold Properties dialog.</td>
</tr>
<tr>
<td>Edit</td>
<td>Lets you edit the selected Datasource Thresholds. When you click this button, Performance Analyst opens the Threshold Properties dialog. If you Edit a Blocked threshold, it loses its blocked status.</td>
</tr>
<tr>
<td>Delete</td>
<td>Lets you delete the selected Datasource Thresholds. When you apply this to a blocked threshold, it is removed from the user thresholds.</td>
</tr>
</tbody>
</table>

Select Datasource(s)

When you have created or edited a threshold template, and you are ready to distribute it, you have the opportunity to apply it to one or more target datasources using the Select Datasources dialog.

To open the Select Datasource(s) dialog box

- Choose Threshold Maintenance... from the Performance Analyst drop-down menu, and then click Apply.

The table below describes the options and functionality on the Select Datasources dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datasources</td>
<td>You can apply the target threshold template to one or more datasources. You can only apply the target threshold template to the platform where it was created.</td>
</tr>
<tr>
<td>Override Datasource’s User Thresholds</td>
<td>Lets you choose which thresholds to use on the target datasource - the thresholds in the Threshold Template or the user-defined thresholds on the target datasource. If you select the check box, Performance Analyst will override any Datasource Thresholds on the target datasource with the thresholds in the Thresholds Template.</td>
</tr>
</tbody>
</table>

Copy Template

The Copy Template dialog lets you copy an existing Threshold Template, rename it, and save it for later use.

To open the Copy Template dialog box
1. Choose Threshold Maintenance... from the Performance Analyst drop-down menu, to open the **Threshold Template Maintenance** dialog.

2. Select the template you want to replicate, and then click Copy.

The table below describes the options and functionality of the **Copy Template** dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Lets you type the name for the new Threshold Template. The default name is Copy of Frankenstein, or whatever it is you named your template.</td>
</tr>
<tr>
<td>Description</td>
<td>Lets you type the description of the new Threshold Template. The default description is simply a repetition of the template name.</td>
</tr>
</tbody>
</table>

**Top Sessions**

The Top Sessions functionality lets you drill-down into the target metric data and quickly pinpoint the heaviest users of I/O and memory. Generally you are taken to the database-specific Expert Guide when you need an explanation of what you are seeing.

**To open Top Sessions**

- Hover your mouse over the little head on the Performance Analyst toolbar and look for the Top Sessions tool-tip.

**To open the Session Details View**

- Double-click any entry in the Top Sessions grid of the Top Sessions view, and the Session Details view opens.

**Top SQL**

The Top SQL view displays all SQL running or executed in the current datasource. You can use the lists and boxes to reorder the display according to your specific needs.

To view Top SQL, do the following:

- On the Performance Analyst toolbar, click the SQL button.
Performance Analyst for Oracle Tutorial

Embarcadero Performance Analyst provides key insight into the complex world of database performance. Running inside the Embarcadero DBArtisan console, or stand-alone in a Web browser, Performance Analyst helps you pinpoint performance problems that threaten a database’s availability or response times. The powerful analysis facilities will satisfy advanced experts, yet novices will find Performance Analyst’s interface easy to use and the expert help a welcome aid to troubleshooting difficult performance issues.

About This Performance Analyst for Oracle Tutorial

This tutorial is intended to help you get started with Embarcadero Performance Analyst.

After completion of this tutorial, you will have the foundation you need to explore the many features and benefits of Performance Analyst. You will have learned how to accurately monitor your database using the most popular performance methodologies in use today. You will know how to drill down into the many layers of database performance and also be able to locate performance issues in your database in a fast and effective manner. Finally, you’ll understand how to fix performance problems using the integration that exists between Performance Analyst and Embarcadero DBArtisan.

This tutorial is divided into 8 sections.

- Session 1: Getting Started With Performance Analyst for Oracle
- Session 2: Using Ratio-based performance analysis in Performance Analyst for Oracle
- Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Microsoft
- Session 4: Using Workload Performance Analysis in Performance Analyst for Oracle
- Session 5: Using SQL Performance Analysis in Performance Analyst for Oracle
- Session 6: Using Operating System Performance Analysis in Performance Analyst for Sybase ASE
- Session 7: Identifying and Getting Help with Performance Problems Using Performance Analyst for Oracle
- Session 8: Fixing Performance Problems Using Performance Analyst for Oracle

You can use this basic tutorial as a roadmap of product highlights.

After starting this tutorial, you can select Help from the menu to find many additional resources that complement and build on many of the activities shown in this brief tutorial.
Topics

- **Session 1: Getting Started With Performance Analyst for Oracle**
- **Session 2: Using Ratio-based performance analysis in Performance Analyst for Oracle**
- **Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Oracle**
- **Session 4: Using Workload Performance Analysis in Performance Analyst for Oracle**
- **Session 5: Using SQL Performance Analysis in Performance Analyst for Oracle**
- **Session 6: Using Operating System Performance Analysis in Performance Analyst for Sybase ASE**
- **Session 7: Identifying and Getting Help with Performance Problems Using Performance Analyst for Oracle**
- **Session 8: Fixing Performance Problems Using Performance Analyst for Oracle**
Session 1: Getting Started With Performance Analyst for Oracle

Download and Install

You can obtain the latest version of Performance Analyst by downloading the DBArtisan software from the Embarcadero Web site at http://www.embarcadero.com/downloads/downloaddbartisan.asp. Performance Analyst runs fully contained within DBArtisan so you will need the DBArtisan product to use Performance Analyst (although Performance Analyst can also run in standalone fashion within a Microsoft Internet Explorer Web browser).

Click Download, and follow the steps indicated. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for 14 days. After that time, a permanent license is needed.

Overview for Performance Analyst for Oracle

The graphic below illustrates all the main elements of the DBArtisan User Interface.

When DBArtisan is connected to an Oracle database, you can open Performance Analyst two ways:

1. On the toolbar, click the Performance Analyst icon.
2. On Utilities menu, select Performance Analyst.

DBArtisan opens Performance Analyst.

Proceed to Session 2: Using Ratio-based performance analysis in Performance Analyst for Oracle
Session 2: Using Ratio-based performance analysis in Performance Analyst for Oracle

Ratio-based analysis has been around for many years, and used to be the only technique database administrators used when they were called on to diagnose the cause of a database slowdown. Performance ratios are very good roll-up mechanisms for busy DBAs, making possible the analysis-at-a-glance approach, however ratios must be computed correctly for them to be meaningful. Key ratios in Performance Analyst are calculated using delta statistics, which is superior to computing ratios with cumulative values. Delta statistics, which are values derived by using the before and after measures in each statistical refresh done in Performance Analyst, lets you see changes in performance metrics that would otherwise be invisible if cumulative statistics were used. Performance Analyst makes it easy to see the ratios that are computed with delta statistics vs. cumulative. A triangle symbol denotes a delta-based statistic, while square symbols represent a cumulative-based measure.

Ratio-based analysis is available for all performance categories (memory, etc.) where ratios can assist in determining the performance level of a database. For example, if you would like to see memory-specific ratios, on the Performance Analyst toolbar click Memory. Performance Analyst displays the Memory home page that showcases all important memory-related ratios.

Obtaining Detail Information for a Ratio Using Performance Analyst for Oracle

A ratio gives you a global picture for a particular performance measure. However, you often need more information regarding a statistical measure so you can make an informed decision.

For example, to view more information for the Buffer Cache Hit Ratio statistic, do the following:

1. On either the Main Home page or the Memory Home page, locate the Buffer Cache Hit Ratio statistic.
2. Position the pointer over the statistic. The pointer changes to a hand symbol.
3. Double-click the left mouse button. Performance Analyst opens the Buffer Cache tab of the memory drill down view.
4. Or right-click the statistic, select Details or Navigate to… > Memory > Buffer Cache. Performance Analyst opens the Buffer Cache tab of the memory drill down view.
Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Oracle

When an Oracle database is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things, or it can be an indicator that a database bottleneck exists. Bottleneck analysis is a valid method of measuring performance because it helps you track where a database and user sessions have been spending their time. If latch contention or heavy table-scan activity has been dragging a database’s performance down, you can use bottleneck analysis to confirm the actual root cause.

Note: For Performance Analyst to show wait times for Oracle wait events, the database configuration parameter TIMED_STATISTICS must be set to TRUE.

Performance Analyst uses two broad areas of metrics to form its bottleneck analysis. The first is the Oracle wait event interface, which displays where the database and user sessions have been bottlenecked. But, when using bottleneck analysis you can not rely only on the information contained in the wait event views that Oracle provides. For example, an object may attempt to extend into another extent of space in a tablespace and yet, be denied if no such free space exists. Such a failure will not be reflected in any wait event, but still represents a very real bottleneck to the database. For this reason, Performance Analyst also shows non-wait event based bottlenecks that represent a very real threat to a database’s availability and performance.

Performance Analyst prominently displays bottleneck analysis on every performance home page. The Main home page, displays a summary of all key bottlenecks threatening the database. You can also see specific bottlenecks for memory, I/O, space, objects, and users by navigating to each home page and viewing the Bottleneck Analysis section for that home page. For example, to see bottlenecks that specifically relate to I/O, do the following:

1. On the toolbar, click the I/O button.
2. Locate the Bottleneck Analysis section at the lower-left portion of the screen.

The I/O bottleneck analysis section displays the top database and log-related Oracle wait events (ranking them by wait time and not actual wait count), along with the most active database files.

Obtaining Detail on System Bottlenecks Using Performance Analyst for Oracle

You can easily obtain more information regarding global bottlenecks that are plaguing a database by drilling down into a particular bottleneck metric. For example, if you would like to see more data regarding the current top system bottlenecks, do the following:
1. Open the Main home page.
2. Double-click the Top System Bottlenecks area.

Performance Analyst opens the System Waits view.

3. Or right-click anywhere in Performance Analyst, point to Users, and then click System Waits.

Performance Analyst opens the System Waits view.

The System Waits view displays critical details regarding all the wait events that Oracle has recorded. You can easily see what events that occurred the most often as well as the events that have accumulated the most wait time.

**Viewing Detail for Session Bottlenecks in Performance Analyst for Oracle**

Not only can you obtain detail information for system bottlenecks, but you can also use Performance Analyst to get drill down information regarding session-level bottlenecks. There are several layers to session-level details you can view.

To see more information regarding session-level waits, do the following:

1. Open the Main home page.
2. Double-click the Top Session Bottlenecks area.

Performance Analyst opens the Session Waits drill down view.

3. Or right-click anywhere in Performance Analyst, point to Users, and then click Session Waits.

Performance Analyst opens the Session Waits drill down view.

When you are in the Session Waits drill down view, to drill further into a session’s details, do the following:

1. In the Historical Waits or Current Waits grid, select a session that appears to be experiencing critical waits.
2. Double-click the session or right-click, and then select Details.

Performance Analyst opens a drill down view that shows key statistics for the selected session, including its current work activities, wait events, and SQL statements.

Proceed to **Session 4: Using Workload Performance Analysis in Performance Analyst for Oracle**
Session 4: Using Workload Performance Analysis in Performance Analyst for Oracle

Key ratios give you a global perspective on database activity. Bottleneck analysis gives you insight into things that are holding up user activity and throughput. But another technique is necessary if a database professional is to really get a handle on what’s occurring inside a badly performing database.

Workload analysis involves the investigation of two critical areas of a database’s performance:

- Session resource consumption and activity
- SQL execution

Without looking at these two key performance categories, you can miss a lot of what could be responsible for perceived performance problems. When performance on a database takes a sudden nosedive, it is not uncommon to find one or two sessions that are causing the bulk of the workload. Finding these processes can be easily accomplished by viewing session metadata coupled with resource consumption and statistical execution statistics.

Pinpointing Top Resource Consumers in Performance Analyst for Oracle

Performance Analyst identifies top resource consumers in a couple of different ways. On the main home page, Performance Analyst highlights the top resource sessions across physical and logical I/O, memory usage, and CPU consumption.

The percentage used across all statistical categories are displayed so you can immediately pinpoint a session that is using all or most of a particular resource. The top resource sessions are also displayed on the memory, I/O, and other home pages as well with a listing for the top sessions for that category. For example, the top memory users appear on the memory home page.

Getting Workload Details Using Performance Analyst for Oracle

Performance Analyst offers several details on top resource sessions in addition to the summaries provided on each home page. A detailed and flexible top sessions view lets you view a summary of all the major resource sessions on the database as well as every critical detail regarding each session connected to the database.
Further drill downs are available that highlights specific details regarding each session’s activities and submitted SQL. To see detailed information regarding a session identified in one of Performance Analyst’s Workload Analysis sections, do the following:

1. In a Workload Analysis display, position the pointer over one of the processes.
2. Double-click the process or right-click, and then select Details.

If you want like to see all key workload analysis metadata for sessions, do the following:

1. On the toolbar, click the Top Sessions button.
2. Or right-click anywhere in Performance Analyst, point to Users, and then click Session Waits.

Proceed to Session 5: Using SQL Performance Analysis in Performance Analyst for Oracle
Session 5: Using SQL Performance Analysis in Performance Analyst for Oracle

SQL-based performance analysis is really a subset of Workload Analysis. Understanding current and historical SQL execution patterns lets you to have the second set of data points necessary to properly perform workload analysis.

Uncovering Resource-intensive SQL in Performance Analyst for Oracle

Performance Analyst offers plenty of insight into SQL performance and execution patterns. Each one of the home pages depicts the most costly SQL statements as determined by a variety of different metrics for that performance category (most physical, logical I/O, etc.) For example, Performance Analyst might show that a single SQL statement is responsible for almost 60 percent of all the physical I/O on the database.

Getting Details on Top SQL with Performance Analyst for Oracle

Getting details on identified SQL statements is easy in Performance Analyst. For example, if you would like to see further information on a SQL statement identified on the Performance Analyst Home page, do the following:

1. In the SQL Analysis section, position the pointer over Hash Values.
2. Double-click or right-click, and then select Details.

Performance Analyst opens the Top SQL summary page that shows a breakdown of all top SQL statements along with their execution statistics.

If you would like to see the full SQL text of a SQL statement, do the following:

1. In the Top SQL Details section, double-click a statement.

Performance Analyst opens the SQL Details tab of the Top SQL view to display the entire SQL statement and the execution metrics. While on this pane, you can also perform an EXPLAIN of the SQL statement and examine its access path information.

Note: To automatically tune a problem SQL statement if you have Embarcadero SQL Tuner installed on your workstation, do the following:

2. On the SQL Details tab, select a problem statement, and then click the Tune SQL button.

SQL Tuner opens and you can begin a tuning session.
Session 6: Using Operating System Performance Analysis in Performance Analyst for Sybase ASE

In many scenarios, an optimally tuned database may not perform well because there are constraints imposed by the system where the database is running. These constraints may include processes competing with the database server for resources (CPU, I/O or Memory), a slow CPU, insufficient I/O devices, and insufficient memory. Performance Analyst allows you to examine the relevant operating system metrics for Windows Platforms (NT /2000/XP/2003) as they relate to Oracle.

To view the operating system metrics of the machine hosting the Sybase ASE server you are monitoring, do the following:

1. Click the OS Performance Analyst toolbar button.

OR

Navigate to the OS Home Page by going to OS, and then Home.

Note: The first time you invoke the OS feature you will be prompted for an operating system login. Please specify the correct operating system, host name, username and password, and protocol.

The Operating System home page has been designed in a similar fashion as the datasource home page. On this page you can see the pertinent operating system metrics displayed in five quadrants broken down into the following categories:

- Resource Usage
- Memory Analysis
- Disk Analysis
- Workload Analysis
- Bottleneck Analysis

Obtaining Details on the Operating System Using Performance Analyst for Oracle

You can easily obtain more information regarding operating system problems that are degrading database performance by drilling down into a particular analysis quadrant. For example if you’d like to see more information regarding the processes running on the host machine, do the following:
1. Navigate to the Performance Analyst Operating System home page.
2. Double-click the Top Memory Process in the Workload Analysis quadrant.

Performance Analyst opens the Processes detail view.

OR

Right-click anywhere in Performance Analyst and select the Navigate to, OS, and then Processes.

The Processes detail tab shows all the processes on the host machine. From this view you can easily determine which processes are showing high marks in I/O or CPU, for example, by simply double clicking on the column headers and sorting the processes in ascending or descending order.

Proceed to Session 7: Identifying and Getting Help with Performance Problems Using Performance Analyst for Oracle
Session 7: Identifying and Getting Help with Performance Problems Using Performance Analyst for Oracle

You do not need to be an advanced expert in performance tuning to spot trouble in a database if you use Performance Analyst. There are a number of mechanisms in the tool that help you quickly locate areas of concern within a database.

Using the Alarm Log

Performance Analyst has a central and flexible alarm log that lists every performance violation found in all monitored databases. Unlike some products that only show you alarms for a particular database, Performance Analyst lists all alarms for each database you are monitoring in one central log so you can see every problem in one place. To view the Performance Analyst Alarm log, do the following:

1. On the toolbar, click the Alarms button.

Once in the Alarm log, you can perform a number of actions including:

- Selecting an alarm and viewing the application page that shows details regarding the metric in violation.
- Filtering the types of alarms shown through the Options dialog.
- Clearing all current alarms.
- Copying or saving the Alarm log into a different format.

To select any of these options, do the following:

1. Position the pointer over any area of the Alarm Log.
2. In the shortcut menu, select an option.

Recognizing Performance Violations

Performance Analyst makes it easy to visually pinpoint performance violations in a database. Any statistic that does not conform to your predefined performance standards is colorized in any view that it appears so you can easily see potential troubleshoots.

The colors used to highlight a particular performance violation depend on the severity of the problem. Performance Analyst uses several layers of performance standards/threshold violations with each layer being represented by a different color. You can control everything regarding threshold violations, including how thresholds are determined, their color representation in Performance Analyst’s display, and more by using the Threshold Template feature of Performance Analyst.
How can Performance Analyst inform you of performance violations in your database if you minimize the product to your desktop and are working on other things? Even if Performance Analyst isn’t right in front of you, it can still let you know that a problem has been found in your database through the sister alarm icon. When Performance Analyst detects a problem in one of your databases, one of the things the product does is enable an alarm icon in your workstation’s systray area that communicates the presence of alarms in your database. So even if the Performance Analyst interface isn’t in sight, the product can let you know that something in your database requires attention.

Creating Threshold Templates

How does Performance Analyst know what to signal as a problem in a database? It uses predefined performance standards that you define and enforce. All of this is accomplished by using Performance Analyst’s Threshold templates. A template is a set of performance metrics and their thresholds that can be reused to enforce performance standards across any number of databases. Embarcadero provides a default performance template that contains nearly all of the most-watched performance statistics so you can begin monitoring with confidence right out of the box. However, you can create your own Threshold templates so you only are alerted to performance violations that are important to you and your particular environment.

To view or create Threshold templates, do the following:

1. On the toolbar, click the Thresholds button.

Performance Analyst opens the Threshold maintenance dialog.

The Threshold Template Properties dialog lets you select the options to add or edit templates, as well as other maintenance options. For example, you can copy the original Embarcadero Threshold template and modify it to fit your own needs. You can control what statistics are sampled for performance violations as well as the levels of severity you would like reported. Once you are satisfied with your template, you can save it and then apply it to one or more datasources in one action to immediately begin enforcing your performance standards.

Getting Help with Performance Problems

As databases become more complex, so do the problems that plague them. Knowing what to do for a particular performance problem can be hard in some cases, but Performance Analyst helps by providing a complete set of expert help that you can use as a guide when performance problems occur. To obtain expert help for any statistic shown in Performance Analyst, do the following:

1. Position the pointer over a statistic that you need help.

2. Right-click and select Help.

The Expert Help gives you a general description of the statistic, the range of values that are considered optimal, and some suggestions on how to fix a problem situation. Expert help can also be invoked for any of the Ratio, Bottleneck, SQL, or Workload Analysis...
sections shown on every home page by clicking on the help icon for that section, which is located at the top right corner of the section.

Proceed to Section 8: Fixing Performance Problems Using Performance Analyst for Oracle

Session 8: Fixing Performance Problems Using Performance Analyst for Oracle

Finding performance problems is one thing, but fixing them is another. Many performance monitors point out a particular problem in a database, but then offer no way to actually correct the situation. Such is not the case with Performance Analyst. Because of its tight integration with DBArtisan, certain problems found in Performance Analyst can be visually corrected by DBArtisan.

If an Oracle tablespace is about to run out of free space, Performance Analyst can issue an alarm that a space shortage exists. Once the space problem has been identified, do the following:

1. On the Space home page toolbar, click the Space button.

2. In the Space Analyst grid, right-click a tablespace, and then select Manage with DBArtisan.

DBArtisan opens an editor where you can perform corrective actions, such as enabling Autoextend for the tablespace, resizing the tablespace’s existing datafile(s), or adding a new datafile for the tablespace.
Oracle Performance Analyst Statistics

This section includes expert help for all Oracle categories and statistics in Performance Analyst views. For detailed information on using the application, see Using Performance Analyst. This guide includes the following sections:

- Home View (Oracle Performance Analyst)
- I/O View (Oracle Performance Analyst)
- Memory View (Oracle Performance Analyst)
- Objects View (Oracle Performance Analyst)
- OS View (Oracle Performance Analyst)
- RAC Detail View (Oracle Performance Analyst)
- Response Time Analysis View (Oracle 10G Only)
- Session Details View (Oracle Performance Analyst)
- Space View (Oracle Performance Analyst)
- Users View (Oracle Performance Analyst)
- Top SQL View (Oracle Performance Analyst)
Home View (Oracle Performance Analyst)

The Home view lets you review availability and overall performance of all monitored databases from a single window. The Home page includes the following sections:

- **Bottleneck Analysis Pane**
- **Key Ratio Analysis Pane**
- **SQL Analysis Pane**
- **Storage Analysis Pane**
- **Workload Analysis Pane**

**Key Ratio Analysis Pane**

Database performance analysts typically use one of two methods for examining the performance levels of a database: Ratio-based or wait/bottleneck-based. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as roll-up mechanisms for at-a-glance performance analysis. Succinctly presented performance ratios can be quickly scanned to see if any database needs immediate attention.

While there are certainly many opinions as to which rules to follow, there are some standards to adhere to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios you examine come from the v$sysstat performance view. The performance view maintains a count of all the occurrences (in the VALUE column) of a particular database incident (in the NAME column) since the database was brought up. For databases that are kept up for long periods of time, these values can grow quite large and impacts how a particular ratio is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

While there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each database’s individual ‘personality’ with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following ratios are used on the Performance Analyst Home page to succinctly communicate the general overall performance levels of the monitored database:

- **Buffer Cache Hit Ratio**
- **Library Cache Hit Ratio**
Dictionary Cache Hit Ratio

Memory Sort Ratio

Parse/Execute Ratio

Buffer Busy Waits

Rollback Contention Ratio

Latch Miss Ratio

Parallel Query Busy Ratio

Free Shared Pool Percent

### Buffer Cache Hit Ratio

Data read from memory will produce end-user response times many times faster than when that same data is read from disk. Keeping physical I/O’s to an absolute minimum is one of the purposes of the Oracle buffer/data cache.

The buffer cache hit ratio is a terrific indicator of how often user requests for data are satisfied through memory vs. being physically read from disk. A number of key counters in Oracle are used to arrive at this statistic. The table below lists them:

<table>
<thead>
<tr>
<th>Counter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB BLOCK GETS</td>
<td>Data read from memory for DML operations.</td>
</tr>
<tr>
<td>CONSISTENT GETS</td>
<td>Data read from rollback segments in memory.</td>
</tr>
<tr>
<td>PHYSICAL READS</td>
<td>Data read physically from disk.</td>
</tr>
<tr>
<td>DIRECT READS</td>
<td>Data read physically from disk that bypasses the buffer cache. Direct reads are filtered out of overall physical reads so an accurate cache hit ratio can be determined.</td>
</tr>
</tbody>
</table>

Dividing the data read from memory by data read from disk yields the cache hit ratio.
Metrics  To help ensure excellent performance, you want to keep your cache hit ratio in the neighborhood of 90% or higher. However, you should be aware that every database has its own ‘personality’ and may exhibit excellent performance with below average readings for the cache hit ratio. You should also be aware that excessive logical I/O activity can produce a very high cache hit ratio while actually degrading overall database performance. Consistently viewed low readings (60% or less) may require tuning attention on the part of the DBA. Note: The db_cache_size parameter value may need to be adjusted. The db_cache_size parameter is dynamic and may be altered without stopping and starting the database instance.

Correction If a problem is found, then: Increase the size of the db_cache_size parameter through use of the ALTER SYSTEM SET db_cache_size command value (take caution to not over-allocate; ensure enough free memory exists on server before increasing value). Monitor the new value to see if performance improves. If using an SPFILE, save the new configuration values so Oracle will reuse them each time the database is stopped and re-started.

Library Cache Hit Ratio

Oracle’s shared pool is made up of two main memory areas - the Library Cache and the Data Dictionary Cache, and offers a number of tuning possibilities.

The library cache holds commonly used SQL statements - basically database code objects. A method for improving performance in Oracle is to encourage the reuse of SQL statements so expensive parse operations may be avoided. The library cache assists this tuning effort.

The library cache hit ratio offers a key indicator in determining the performance of the shared pool. It shows how often SQL code is being reused by other database users vs. the number of times a SQL statement is broken down, parsed, and then loaded (or reloaded) into the shared pool.
A high library cache hit ratio is a desirable thing. You should strive for a hit ratio between 95-100%, with 99% being a good performance benchmark for code reuse. Note that when a database is first started, the library cache hit ratio will not be at an optimal level because all code being used will be relatively new, and as such, must be parsed and placed into the shared pool. If, however, after a solid hour or two of steady database time, the library cache hit ratio has not increased to desirable levels, you should look into the possibility of increasing the shared_pool_size parameter. Other red flags that can indicate a too small shared pool include:

- A wait count for the event 'latch free' of ten or greater
- The library cache wait count of two or greater.

These indicators can be tracked with Performance Analyst's Bottleneck and Wait detail views. A way of improving the library cache hit ratio is by encouraging code reuse through the implementation of bind variables. Discouraging hard coded literals in application code and instead making use of variables bound at run time aids in the reuse of SQL code that is maintained in Oracle's shared pool. Note that bind variables can have an affect on the cost-based optimizer though. A second way is to pin frequently used code objects in memory so they will always be there when needed. This can be accomplished through the use of the system supplied DBMS_SHARED_POOL package. You can use Performance Analyst to view objects in the shared pool that are always present and/or have increasing reload numbers to help identify objects that are good candidates for pinning.

If a problem is found, then: Increase the size of the shared_pool_size parameter through use of the ALTER SYSTEM SET shared_pool_size command value (take caution to not over-allocate; ensure enough free memory exists on server before increasing value). Monitor the new value to see if performance improves. If using an SPFILE, save the new configuration values so Oracle will reuse them each time the database is stopped and re-started. If you determine that SQL literals are causing SQL to not be reused, you can: Change the cursor_sharing parameter to FORCE by using the ALTER SYSTEM SET cursor_sharing=FORCE command. Monitor database to see if parse activity is reduced and library cache reloads shrink. If using an SPFILE, save the new configuration values so Oracle will reuse them each time the database is stopped and re-started. If using an Init.ora file, add the cursor_sharing=FORCE parameter to the file.

**Dictionary Cache Hit Ratio**

Oracle's shared pool offers an number of tuning possibilities and is made up of two main memory areas:

1. Library Cache
2. Data Dictionary Cache

The dictionary cache hit ratio offers another key indicator in determining the performance of the shared pool. It shows how often object definitions are found in memory vs. having to read them in from disk. Because Oracle references the data
dictionary many times when an SQL statement is processed, it is imperative that as much of this vital reference information be kept in RAM as possible.

Location Oracle Performance Analyst Statistics > Home View (DBArtisan - Oracle Performance Analyst) > Key Ratio Analysis PaneOracle Performance Analyst Statistics > Memory View (Oracle Performance Analyst) > Key Ratio Analysis pane

Metrics Just as with the library cache, a high data dictionary cache hit ratio is desirable. Strive for a hit ratio between 90-100%, with 95% being a good performance benchmark.

NOTE: When a database is first started, the data dictionary cache hit ratio is not at an optimal level because all references to object definitions are relatively new, and as such, must be placed into the shared pool. Look for hit ratios in the eighty’s for new database startups. If, however, after a solid hour or two of steady database time, the data dictionary cache hit ratio has not increased to desirable levels, increase the shared_pool_size parameter. Databases supporting applications that involve large number of objects (such as an Oracle Financials installation) should have larger than normal shared pools to support the required object definitions. Although each parameter is not individually tunable (it was in Oracle6), you can see which area of the dictionary cache could be pulling the overall hit ratio down.

Correction If a problem is found, do the following: Increase the size of the shared_pool_size parameter through use of the ALTER SYSTEM SET shared_pool_size command value. Take caution to not over-allocate; ensure enough free memory exists on server before increasing value. Monitor the new value to see if performance improves. If using an SPFILE, save the new configuration values so Oracle reuses them each time the database is stopped and re-started.

Memory Sort Ratio

Oracle9i or later has the option of running automatic PGA memory management. Oracle has introduced an Oracle parameter called pga_aggregate_target. When this parameter is set and you are using dedicated Oracle connections, Oracle ignores all of the PGA parameters in the Oracle file, including sort_area_size, hash_area_size and sort_area_retained_size. Oracle recommends that the value of pga_aggregate_target be set to the amount of remaining memory (less a 10% overhead for other server tasks) on a server after the instance has been started.
If the memory sort ratio falls below 90%, and you are on Oracle9i or later, investigate the use of pga_aggregate_target. Once the pga_aggregate_target has been set, Oracle automatically manages PGA memory allocation, based on the individual needs of each Oracle connection. Oracle9i or later allows the pga_aggregate_target parameter to be modified at the instance level with the alter system command, thereby lets you dynamically adjust the total RAM region available to Oracle9i. Oracle9i also introduced a new parameter called workarea_size_policy. When this parameter is set to automatic, all Oracle connections benefits from the shared PGA memory. When workarea_size_policy is set to manual, connections allocates memory according to the values for the sort_area_size parameter. Under the automatic mode, Oracle tries to maximize the number of work areas that are using optimal memory and uses one-pass memory for the others.

Correction
If you find a problem, do the following: Edit the Init.ora or SPFILE file for the database. Increase the amount of sort_area_size to a higher value. Take caution to not over-allocate; ensure enough free memory exists on server before increasing value. EVERY user receives this amount for sorting. Cycle the Oracle server when possible to allow the new value to take effect. Monitor new value to see if performance improves. In addition to increasing the amount of memory devoted to sorting, find inefficient SQL that cause needless sorts. For example, UNION ALL does not cause a sort whereas UNION does in an SQL query (to eliminate duplicate rows). DISTINCT is frequently misapplied to SQL statements and causes unnecessary sort actions. There are times you simply cannot stop sort activity. This being the case, try to keep it in memory whenever possible. However, large data warehousing systems oftentimes simply exhaust RAM sort allotments, so if disk sorts must occur, try to ensure three things: Your user’s TEMPORARY TABLESPACE assignment is not the SYSTEM tablespace, which is the default assignment. NOTE: For Oracle9i or later, you can specify a default tablespace other than SYSTEM for every user account that is created. The TEMPORARY TABLESPACE assigned to your users is placed on a fast disk. The TEMPORARY TABLESPACE has the tablespace parameter TEMPORARY assigned to it, which allows sort activity to be performed in a more efficient manner.

Parse/Execute Ratio
Each time a new SQL statement is submitted to Oracle, the kernel must ‘parse’ the statement, which involves syntax checks, security checks, and object validations. The Parse/Execute Ratio shows the percentage of SQL executed that did not incur a hard parse.

Note: This statistic is available on the Home page, Memory home page, and the Users home page.
Metrics

Seeing low values might indicate that users are firing SQL with many hard-coded literals instead of using bind variables within an application. High values (90% and greater) generally indicate Oracle is saving precious CPU by avoiding heavy parse tasks.

Correction

The best way to reduce unnecessary parse activity is to encourage SQL statement reuse. This can be done by promoting SQL execution through the use of stored procedures or applications where bind variables can be used. Oftentimes, literals in otherwise identical SQL statements can cause unneeded parse work for Oracle. The use of bind variables can counter that problem. If you determine that SQL literals are causing SQL to not be reused, do the following: Change the cursor_sharing parameter to FORCE by using the ALTER SYSTEM SET cursor_sharing=FORCE command. Monitor database to see if parse activity is reduced and library cache reloads shrink. If using an SPFILE, save the new configuration values so Oracle reuses them each time the database is stopped and re-started. If using an Init.ora file, add the cursor_sharing=FORCE parameter to the file.

Buffer Busy Waits

Buffer busy waits occur when a process needs to access a data block in the buffer cache, but cannot because it is being used by another process. A wait event generally happens because a buffer is being read into the buffer cache by another process or the buffer is in the buffer cache, but cannot be switched to a compatible mode immediately.

Correction

You can use the automatic segment management feature in Oracle9i locally-managed tablespaces to help make free list problems a thing of the past. Using an UNDO tablespace in 9i or later can help remedy any rollback contention problem. You can also obtain which objects have actually experienced buffer busy waits in Oracle9i or later by querying the sys.v_$segment_statistics. This view is not populated unless the configuration parameter statistics_level is set to TYPICAL or ALL.

Rollback Contention Ratio

Rollback segments are used by Oracle to hold data needed to rollback any changes made through inserts, updates, or deletes to various Oracle objects. They also allow Oracle to have read consistency for long running queries, are used for recovery
purposes, and play a role during exports of database information. In a heavy transaction processing environment, rollback segments are accessed continuously and therefore are subject to contention problems. The Rollback Contention Ratio helps identify contention occurring on the system relating to rollbacks.

**Location** Oracle Performance Analyst Statistics > Home View (DBArtisan - Oracle Performance Analyst) > Key Ratio Analysis Pane

**Metrics** Overall, if the rollback contention ratio approaches 1% or more, create more rollback segments. Also consider creating a specialized, larger, rollback segment to be used by long running transactions. Doing so alleviates dynamic rollback extensions and cuts down heavily on ORA-01555 Snapshot Too Old errors.

**Correction** Begin by creating new rollback segments and altering them to be online for use. Then monitor the overall contention ratio to see if it begins to drop. If you are using Oracle9i or later, consider using an UNDO tablespace and allowing Oracle to automatically control rollback segment management.

### Latch Miss Ratio

Protecting the many memory structures in Oracle's SGA are latches. They ensure that one and only one process at a time can run or modify any memory structure at the same instant. Much more restrictive than locks (which at least allow for some collective user interaction), latches have no queuing mechanism - so either you get it or you do not and are forced to continually retry.

The latch miss ratio defines the number of times a process obtained a willing-to-wait latch vs. missing the attempt.

**Location** Oracle Performance Analyst Statistics > Home View (DBArtisan - Oracle Performance Analyst) > Key Ratio Analysis Pane

**Metrics** If the latch miss ratio exceeds 1%, you should take action to resolve the amount of latch contention.

**Correction**

Examine the details regarding the latch contention. Increasing the shared_pool_size can assist in latch problems also. The table below describes latches:
Latch | Description
--- | ---
Cache buffer chain latch | Protects paths to database block buffers in the buffer cache. High I/O loads tend to cause contention for this latch. You can alleviate contention somewhat by adding more buffers to the cache (through the `db_block_buffers` or `db_cache_size` parameter) or by adding more LRU latch chain latches with the `db_block_lru_latches` parameter.

Library cache latches | Protects cached SQL statements in the library cache area of the Oracle shared pool. Contention for this latch is the usual result of literals being used for SQL statements instead of bind variables.

### Parallel Query Busy Ratio

Oracle's parallel query feature, when used properly, allows for terrific increases in performance for many SQL and utility operations. Parallel operations can be introduced through SQL hints, specified in an object's DDL, or used in command line arguments for utility programs (like SQL*Loader). To effectively service parallel query requests, ensure that enough query servers exist in the database instance. The Parallel Query Busy Ratio is an indicator of how busy all the servers are on the database in question.

**Metrics** If the Parallel Query Busy Ratio approaches 80-90%, add more query servers to the database, or examining parallel requests to ensure they are being used in an efficient and necessary manner.

**Correction** To fix, do the following: Edit the `Init.ora` file or `SPFILE` for the database. Increase the amount of `parallel_max_servers` to a higher value. Cycle the Oracle server when possible to allow the new value to take effect. Monitor new value to see if performance improves. You can also investigate the use of the `parallel_automatic_tuning` parameter.

### Free Shared Pool Percent

Oracle's shared pool need not use all of the memory given to it through the `shared_pool_size` parameter. If the database does not have many object and code definitions to reference, then the shared pool can contain an abundance of free memory that is not being used.
Under-allocating the shared pool size can have a serious impact on your database’s performance, but over-allocating the shared pool can have run time ramifications as well. If you have a good chunk of memory allocated to the Oracle shared pool that is never used, it might be more of a performance enhancement to reduce the shared pool amount and instead give the memory to the buffer/data cache, or even back to the operating system itself. In terms of knowing when to reduce the shared pool, a good benchmark is continually seeing 2-3MB of free memory. On the other hand, if after an hour or so of beginning database operation, you see that virtually no free memory is left in the shared pool, or you are seeing ORA-4031 errors (that indicate definitions cannot find enough contiguous free space in the shared pool), increase the pool by 10% or more.

Correction If you continuously see little or no free memory in the shared pool, do the following: Increase the size of the shared_pool_size parameter through use of the ALTER SYSTEM SET shared_pool_size command value. Take caution to not over-allocate; ensure enough free memory exists on server before increasing value. Monitor the new value to see if performance improves. If using an SPFILE, save the new configuration values so Oracle reuses them each time the database is stopped and re-started. You can also use the ALTER SYSTEM FLUSHED SHARED_POOL command to remove all objects from the shared pool and start with a clean slate.

Bottleneck Analysis Pane

When an Oracle database is running, every connected process is either busy doing work or waiting to perform work. A process that is waiting can mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. And this is where wait-based or bottleneck analysis comes into play. DBAs used this form of performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps you track where a database has been spending its time. If latch contention or heavy table scan activity has been dragging a database’s performance down, you can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, you can determine which sessions and objects are causing the problem.

For wait event analysis to be properly carried out, it is imperative that the timed_statistics initialization parameter be set to TRUE. By default this parameter is set to FALSE, which disallows the collection of wait times for each wait event defined to the Oracle engine. For one to really understand the impact of wait events on database performance, you need to discover what the database is or has been waiting on, and the durations of the waits. Having both allows a complete picture to be formed regarding the magnitude of wait-initiated performance degradations. Almost all Oracle experts now agree that allowing the collection of timing statistics adds little if anything to database overhead, so setting timed_statistics to TRUE should not be a worry. The
Performance Analyst Home page identifies the top system and session waits that can decrease performance.

When using bottleneck analysis, you cannot rely only on the information contained in the wait event views that Oracle provides. For example, an object can attempt to extend into another extent of space in a tablespace and yet be denied if no such free space exists. Such a failure is not reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that you cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain an accurate performance risk assessment. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system. The Performance Analyst Home page displays space-related bottlenecks as well as other sources of contention/bottlenecks that can decrease the overall performance of your system.

The following bottleneck indicators are used on the Performance Analyst Home page to succinctly communicate the general overall performance level of the monitored database:

- Top System Bottlenecks
- Top Session Bottlenecks
- Problem Tablespaces
- Problem Objects
- Current Object Blocks
- Enqueue Waits
- Free List Waits
- Storage Analysis Pane

**Top System Bottlenecks**

When viewing wait statistics, there are many levels of detail that you can view. The first level is the system view, which provides a global, cumulative snapshot of all the waits that have occurred on a system. Viewing these numbers can help you determine which wait events caused the most commotion in a database so far. The Top System Bottlenecks section identifies the top waits that have occurred on the Oracle database based on the number of waits per event.

For Oracle 10g only you see a graph that provides a historical look at the last hour and allows you to see what wait classes experienced the most wait activity in terms of time waited. To get detail into which wait events have accumulated the most time, you can drill down into the System Waits view.
Correction Appendix A in the Oracle Reference manual contains a listing and description of every current wait event defined in Oracle. DBAs unfamiliar with what each event represents should keep this listing close by as they examine wait-based event metrics. For example, a ‘db file scattered read’ event is typically indicative of table scan operations. If you see many of these events, then you can begin to see if large table scans are occurring in the database. Like the ‘db file scattered read’ event, each wait event has its own meaning and individual end-resolution diagnosis. After looking at system-level wait activity, you can discover which current connections are responsible for waits at the system level. Performance Analyst reports on historical and current wait events at the session level, making this investigation easy to accomplish.

Top Session Bottlenecks

When viewing wait statistics, there are many levels of detail that you can view. The first level is the system view, which provides a global, cumulative snapshot of all the waits that have occurred on a system. The second level is a historical look at waits from a session level. The third is which sessions are currently experiencing waits. The Top Session Bottlenecks section identifies the top sessions that are currently waiting, based on their wait time in seconds.

Problem Tablespaces

The Problem Tablespaces metric is a count of all tablespaces in the database whose free space percentage amount has fallen below a user-defined limit.
A rule of thumb for dynamic tablespaces (those with growing objects) is to keep a minimum of 10-15% free space available for object growth.

There are two ways to prevent a tablespace from running out of available free space:

- **Turn AUTOEXTEND on for the underlying tablespace's datafiles.** This allows them to automatically grow when free space in the datafile has been exhausted.

- Using the `ALTER TABLESPACE ... ADD DATAFILE...` command, you can manually add a new datafile to a tablespace that is about to run out of available free space.

**Problem Objects**

The Problem Objects statistic is a count of all objects in the database that are in danger of reaching their maximum extent limit or cannot allocate their next extent of free space because of a lack of overall or contiguous free space in their parent tablespace.

Depending on the situation, there are a number of things you can do to prevent object extent problems:

- **Turn AUTOEXTEND on for the underlying parent tablespace's datafiles.** This allows a tablespace to automatically grow when free space in the datafile has been exhausted, and allows an object to extend even when little or no current free space is available.

- Using the `ALTER TABLESPACE ... ADD DATAFILE...` command, you can manually add a new datafile to a tablespace that is about to run out of available free space.

- You can alter an object that is at or near their maximum extent limit so that the object has unlimited extents.

- You can use locally-managed tablespaces to ensure that no object ever reaches its maximum extent limit, because all objects are allowed unlimited extents.

- An object can be reorganized into another tablespace or reorganized in general to reduce the number of extents the object currently takes up.

**Current Object Blocks**

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Although Oracle supports unlimited row-level locking, blocking lock situations do crop up. Blocks are most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency.

**Note:** This statistic is also called Sessions Blocked on the Users View (Oracle Performance Analyst) and Session Blocks on the Objects View (Oracle Performance Analyst) page.
Metrics

Once discovered, a blocking lock situation can normally be quickly remedied. You can issue a KILL against the offending process, which eliminates the user’s stranglehold on the objects they were accessing. Other user processes then nearly always complete in an instant. Discovering the blocked lock situation is made easier by using tools like Performance Analyst, but preventing the blocking lock situation in the first place is where it gets tricky. You can look at the Users View (Oracle Performance Analyst) detail and view all current blocking locks to see exactly which sessions are holding the currently restrictive locks. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. Most DBAs who have had to face Oracle Forms applications have suffered through the dreaded SELECT … FOR UPDATE statements that place unnecessary restrictive locks on nearly every read operation, and know all too well that good coding practice is important. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do.

**Enqueue Waits**

An enqueue is an advanced locking device that allows multiple database processes to share certain resources. Enqueue waits typically occur when sessions wait to be granted a requested lock. Sometimes these locks are internal Oracle locks while other times they could be locks for rows of data. Enqueues are issued implicitly by Oracle.

Correction

Removing contention for enqueues is almost always an application design issue. If many enqueue waits are seen, this normally indicates either contention for certain rows in the database, or the result of database-initiated lock escalation. Examine the use of indexes to make sure all referencing foreign keys are indexes and that SQL is tuned to not tarry over rows in the database during modification operations.

Enqueue waits can also be the result of space management tasks (such as objects extending) and disk sorts (mainly in tablespaces that do not make use of the TEMPORARY tablespace parameter).

**Free List Waits**

Free lists are lists of Oracle data blocks that contain free space for an Oracle object. Every table has at least one free list. Free lists are used to locate free blocks of space
when a request is made of a table for the insertion of a row. Free list contention can reduce the performance of applications when many processes are involved in the insertion of data to the same table.

**Location** Oracle Performance Analyst Statistics > Home View (DBArtisan - Oracle Performance Analyst) > Top Session Bottlenecks > Objects View (Oracle Performance Analyst) > Bottleneck Analysis Pane

**Metrics** If consistent numbers for free list waits continue to appear, add additional free lists to the most dynamic database objects through the use of the STORAGE parameter. Another indicator of insufficient free lists are consistent, non-zero numbers for the buffer busy wait event.

**Correction** If free list waits are observed, add more free lists to tables and indexes with high insert rates. For Oracle9i or later, objects can be created inside of locally-managed tablespaces that use the automatic segment management feature, which entirely does away with free lists.

### Storage Analysis Pane

While DBAs focus on memory settings and tuning SQL, storage problems can play a major role in wrecking an otherwise well-running database.

Storage problems generally take one of two forms:

1. **Hit-the-wall**, which can bring things to a complete standstill.
2. **Performance vampire**, which slowly drains the performance of a database over time.

Storage problems have the capability to bring the curtain down on a database very quickly, as in the case of an archive log destination running out of free space. But storage problems can also silently work behind the scenes to slowly but surely rob a database of its performance. For example, you can access a hub table in a busy database when an application is first given life, but over time, if it develops a heavy migrated row problem, it can cause things to run very differently.

The Storage Analysis section of the Performance Analyst Home page reports on the total used and free space of all tablespaces in the database as well as whether the database is running in Archive Log mode. For more detailed information on database space, use the Performance Analyst Space View (Oracle Performance Analyst).

### Total Used Space/Total Free Space

These statistics represent the total used and free space available in all tablespaces/datafiles in the database. Although good to know, a more detailed listing by tablespace is needed to determine where any actual space shortages exist in the database.
Metrics  If any one tablespace begins to approach 90% used (and the objects contained within it are dynamic and growing as opposed to static), take action to prevent any future space allocation errors.

Correction  Here are some things you can do to prevent a tablespace from running out of available free space: Turn AUTOEXTEND on for the underlying tablespace's datafiles. This allows them to automatically grow when free space in the datafile has been exhausted. Using the ALTER TABLESPACE ... ADD DATAFILE... command, you can manually add a new datafile to a tablespace that is about to run out of available free space.

Archive Log

Oracle can be placed into archivelog mode, which tells the database to make copies of the online redo log files for point-in-time recovery purposes. The Archive Log statistic displays whether the database is running in archivelog mode or not. This information is displayed in the Storage Analysis section of the Performance Analyst Home page. For more information, see Storage Analysis Pane.

SQL Analysis Pane

Much of a database's overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end user response times. SQL statements that use much memory can also cause a problem in a database.

Before you can identify problem SQL in your database, you have to ask the question, “What is bad SQL?” What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every Oracle professional's satisfaction. The table below lists some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:
<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overall Response Time</td>
<td>The amount of time the query took to parse, execute, and fetch the data needed to satisfy the query. It should not include the network time needed to make the round trip from the requesting client workstation to the database server. This statistic is available in Oracle9i or later.</td>
</tr>
<tr>
<td>CPU Time</td>
<td>The amount of CPU time the query took to parse, execute, and fetch the data needed to satisfy the query.</td>
</tr>
<tr>
<td>Physical I/O</td>
<td>This is often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user’s request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at a statements’ logical I/O as well.</td>
</tr>
<tr>
<td>Logical I/O</td>
<td>The number of memory reads the query took to satisfy the user’s request. The goal of tuning I/O for a query should be to examine both logical and physical I/O, and use appropriate mechanisms to keep both to a minimum.</td>
</tr>
<tr>
<td>Repetition</td>
<td>The number of times the query has been executed. A problem in this area is not as easy to spot as the others unless you know your application well. A query that takes a fraction of a second to execute can still cause a headache on your system if it is executed erroneously (for example, a query that executes in a runaway PL/SQL loop) over and over again.</td>
</tr>
</tbody>
</table>

There are other criteria that you can examine like sort activity or access plan statistics (that show items like Cartesian joins and the like), but more often than not, these measures are reflected in the criteria listed above. Fortunately, Oracle records all the above measures (some only in 9i), which makes tracking the SQL that has been submitted against an Oracle database much easier.

**Metrics**

When you begin to look for inefficient SQL in a database, there are two primary questions you want answered:

1. What HAS been the worst SQL that has historically run in my database?
2. What IS the worst SQL that is running right now in my database?

When troubleshooting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It can be that the query is in an inefficient PL/SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.

There is the possibility that the SQL statement just is not tuned well. To determine that, you can go further into Performance Analyst’s Top SQL view and, if you have
Embarcadero SQL Tuner installed, you can port the SQL over to SQL Tuner to better optimize the statement.

**Workload Analysis Pane**

When your database experiences performance slowdowns, you should answer the following:

- Who is currently connected to the database?
- What resources are they using?
- What are they currently executing?

The Workload Analysis section of the Performance Analyst Home page provides insight into the leading resource hogs of a database as well as a count of total active and inactive processes. You can view detailed information into what each leading session is currently involved with.

The Workload Analysis section of the Home page includes:

- **Top Processes**
- **Active User Processes**
- **Inactive User Processes**

The buffer cache hit ratio is an indicator of how often user requests for data are satisfied through memory vs. being physically read from disk. Data read from memory produces user response times many times faster than when that same data is read from disk. Keeping physical I/Os to an absolute minimum is one of the Oracle buffer cache’s purposes in life.

The table below describes the key counters Performance Analyst uses to calculate the buffer cache hit ratio:

<table>
<thead>
<tr>
<th>Key Counter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB BLOCK GETS</td>
<td>Data read from memory for DML operations.</td>
</tr>
<tr>
<td>CONSISTENT GETS</td>
<td>Data read from rollback segments in memory.</td>
</tr>
<tr>
<td>PHYSICAL READS</td>
<td>Data read physically from disk.</td>
</tr>
<tr>
<td>Direct Reads</td>
<td>Data read physically from disk that bypasses the buffer cache. Direct reads are filtered out of overall physical reads so an accurate cache hit ratio can be determined.</td>
</tr>
</tbody>
</table>

Dividing the data read from memory by data read from disk yields the cache hit ratio.

**Metrics**
To help ensure excellent performance, you want to keep your cache hit ratio in the neighborhood of 90% or higher. However, every database has its own ‘personality’ and can exhibit excellent performance with below average readings for the cache hit ratio. Excessive logical I/O activity can produce a very high cache hit ratio while actually degrading overall database performance.

Investigate consistent low readings of 60% or less.

**Note:** The db_cache_size parameter may need adjusting. The db_cache_size parameter is dynamic and can be altered without stopping and starting the database instance.

**Correction**

If a problem is found, do the following:

- Increase the size of the db_cache_size parameter through use of the ALTER SYSTEM SET db_cache_size command value (take caution to not over-allocate; ensure enough free memory exists on server before increasing value).
- Monitor the new value to see if performance improves.
- If using an SPFILE, save the new configuration values so Oracle reuses them each time the database is stopped and re-started.

**Top Processes**

When the database population as a whole experiences a system slowdown, it is not uncommon to find one or two users who are responsible for bringing the system to its knees. In the best of worlds, users have an evenly divided amount of memory usage, disk I/O, CPU utilization, and parse activity. Unfortunately, this is not usually the case. Users submit large batch jobs during peak OLTP activity, or when sessions that are firing off untuned queries on a critical system.

If you are seeing a slowdown in your database, and cannot seem to find a root cause, one thing to examine is the resource consumption of the leading sessions on a system. A handful of users can overwhelm the I/O capabilities of Oracle (through untuned queries or runaway batch jobs) or hammer the CPU or memory structures of the database and server.

Performance Analyst makes it easy to pinpoint the top sessions by showing the leading processes at the physical I/O, logical I/O, memory, and CPU usage levels.
Active User Processes

The Active User Processes statistic is the total number of active and open threads reported in the database. Active Sessions displays the number of processes actively performing work.

For more information, see Inactive User Processes.

Inactive User Processes

This metric is the total number of threads logged on to the database that are idle at the current time.

Metrics A large number of inactive users could indicate user sessions that have mistakenly been left logged on. Because each user thread consumes a portion of memory on the Oracle server, sever any sessions not needing a connection to reduce resource usage.

Correction Double-click this statistic to open the Top Sessions Tab of the Users Detail page. On this tab you can check sessions that have many seconds idle and/or that have been logged on for very long periods of time as indicated by the logon time column. After verifying that the session is no longer necessary, you can KILL the session. For more information, see Active User Processes.
Memory View (Oracle Performance Analyst)

In addition to a Home page, the Memory category of Oracle Performance Analyst includes the following tabbed pages:

- Buffer Cache Tab
- Buffer Pools Tab
- Dictionary Cache Tab
- Latch Activity Tab
- Library Cache Tab
- Shared Pool Tab
- PGA Tab

Home

The Memory home page includes the following sections:

- Bottleneck Analysis pane
- Key Ratio Analysis pane
- SGA Analysis Pane
- SQL Analysis Pane
- Workload Analysis Pane

Key Ratio Analysis pane

Object-related database activity can be examined using both ratio-based and wait/bottleneck-based analysis. Ratio-based analysis involves examining a number of key database ratios and statistical readings that can be used to indicate how active certain object types are. Performance ratios serve as roll-up mechanisms for busy DBAs to use for at-a-glance performance analysis.

When using ratio-based analysis, there are some standards to adhere to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that you examines come from the v$sysstat performance view. The performance view maintains a count of all the occurrences (in the VALUE column) of a particular database incident (in the NAME column) since the database was brought up. For databases that are kept up for long periods of time, these values can grow quite large and impacts how a particular ratio is interpreted. However, if delta statistics are used (taking, for a specified sampling
period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each database’s individual ‘personality’ with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead you to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following memory ratios are used on the Performance Analyst Memory home page to succinctly communicate the general overall memory performance levels of the monitored database. They duplicate statistics shown on the Home page. For detailed descriptions of those statistics, see Key Ratio Analysis Pane.

- Buffer Cache Hit Ratio
- Library Cache Hit Ratio
- Dictionary Cache Hit Ratio
- Memory Sort Ratio
- Free Shared Pool Percent
- Parse/Execute Ratio

**Bottleneck Analysis pane**

When an Oracle database is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. You can use Bottleneck Analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Memory bottlenecks can definitely cause performance degradation in an otherwise well-running database. Typically, these bottlenecks center around Oracle’s buffer/data cache, library cache, and occasionally log buffer memory regions. To help you identify such problems, the following statistics are presented on the Memory home page:

- Free Buffer Wait Average
- Object Reloads
- Redo Log Space Waits
- Redo Log Space Wait Time
- Top Latch Misses

The following statistic, available on this pane, duplicates a statistic available on the Key Ratio Analysis Pane of the Home View (Oracle Performance Analyst) page:
- **Buffer Busy Waits**

### Free Buffer Wait Average

There are times when a user must wait to obtain a clean buffer in the buffer/data cache. The free buffer wait average provides a metric that communicates the average number of tree buffer waits.

**Location** [Oracle Performance Analyst Statistics](#) > Memory View (Oracle Performance Analyst) > Home > Bottleneck Analysis pane

**Metrics** Seeing consistent non-zero numbers for the free buffer wait average might indicate an undersized data/buffer cache.

**Correction** If the Object Reloads statistic, along with other shared pool metrics, indicates an undersized shared pool, you can do the following depending on the version of Oracle you are running: If a problem is found: Increase the size of the shared_pool_size parameter through use of the ALTER SYSTEM SET shared_pool_size command value. Take caution to not over-allocate; ensure enough free memory exists on server before increasing value. Monitor the new value to see if performance improves. If using an SPFILE, save the new configuration values so Oracle reuses them each time the database is stopped and re-started. If you suspect that there are hot code objects that would benefit from being pinned into the shared pool, then you can go into shared pool details using Performance Analyst’s monitors. You can easily spot the general code object types or specific objects that should be pinned in the pool from these monitors. Once identified, you can use the dbms_shared_pool package to pin the hot code objects into RAM.

### Object Reloads

When a SQL statement or code object (stored procedure, trigger, etc.) is executed for the first time, Oracle loads the code definition into the shared pool. If the statement or code object is executed again, Oracle can reuse the object definition in memory, and thereby shorten execution time.

If a code object is aged out of the shared pool, and then re-requested, Oracle must load the object back into the pool. Such activity can lead to reduced response times. The Object Reloads statistic provides you with a count of how many objects have been reloaded back into the shared pool.
Metrics

Seeing consistent non-zero numbers for object reloads could indicate a too small shared pool or that there are hot code objects that should be pinned in the shared pool so they cannot be removed.

Correction

If the Object Reloads statistic, along with other shared pool metrics, indicates an undersized shared pool, you can do the following depending on the version of Oracle you are running:

- If a problem is found:
  - Increase the size of the `shared_pool_size` parameter through use of the `ALTER SYSTEM SET shared_pool_size` command value. Take caution to not over-allocate; ensure enough free memory exists on server before increasing value.
  - Monitor the new value to see if performance improves.
  - If using an SPFILE, save the new configuration values so Oracle reuses them each time the database is stopped and re-started.

If you suspect that there are hot code objects that would benefit from being pinned into the shared pool, then you can go into shared pool details using Performance Analyst’s monitors. You can easily spot the general code object types or specific objects that should be pinned in the pool from these monitors. Once identified, you can use the `dbms_shared_pool` package to pin the hot code objects into RAM.

Redo Log Space Waits

The Oracle database is able to manage recovery by recording all changes made to a database through the use of redo log files. Oracle writes modifications made to a database to these files that have the capability to be archived off to another medium for disaster recovery. The background process that performs these operations is Oracle’s Log Writer (LGWR). There is a buffer area in Oracle’s System Global Area (SGA) that is used to reduce redo log file I/O, whose size, or lack thereof, can affect performance in a busy system. Sometimes a user process must wait for space in this redo log buffer. Oracle uses the log buffer area to cache redo entries prior to writing them to disk, and if the buffer is not large enough for the redo entry load, waits can occur.
Redo Log Space Wait Time

The Oracle database is able to manage recovery by recording all changes made to a database through the use of redo log files. Oracle writes modifications made to a database to these files that have the capability to be archived off to another medium for disaster recovery. The background process that performs these operations is Oracle's Log Writer (LGWR). There is a buffer area in Oracle’s System Global Area (SGA) that is used to reduce redo log file I/O, whose size, or lack thereof, can affect performance in a busy system. Sometimes a user process must wait for space in this redo log buffer. Oracle uses the log buffer area to cache redo entries prior to writing them to disk, and if the buffer is not large enough for the redo entry load, waits can occur.

Top Latch Misses

Latches protect the many memory structures in Oracle’s SGA. They ensure that one and only one process at a time can run or modify any memory structure at the same instant.
More restrictive than locks (which at least allow for some collective user interaction), latches have no queuing mechanism.

The Top Latch Misses chart indicates the top latch waits as ranked by total misses.

Location  Oracle Performance Analyst Statistics > Memory View (Oracle Performance Analyst) > Home > Bottleneck Analysis pane

Metrics  Seeing increasing numbers for the same latch miss can require further accessing session latch details, which can be accomplished inside Performance Analyst.

Correction  The remedy for latch misses depends on the latch itself. Buffer chain latches, for example, are indicative of high I/O rates in databases. Increasing the buffer/data cache can help as might adding more buffer LRU chain latches by increasing the db_block_lru_latches parameter. Library cache latch misses are oftentimes produced by non-reused SQL in the shared pool. Increasing the shared_pool_size can help, but a better remedy might be changing SQL to use bind variables or setting the cursor_sharing parameter to FORCE.

SQL Analysis Pane

Much of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end user response times. SQL statements that use much memory can also cause a problem in a database. The SQL Analysis for memory shows what SQL statements have consumed the largest percentages of shareable, persistent, and runtime memory.

Before you can identify problem SQL in your database, you have to ask the question, “What is bad SQL?” What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every Oracle professional’s satisfaction. The table lists some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:
Criteria | Description
--- | ---
Overall Response (Elapsed) Time | The time the query took to parse, execute, and fetch the data needed to satisfy the query. It should not include the network time needed to make the round trip from the requesting client workstation to the database server. This statistic is available in Oracle9i or later.

CPU Time | The CPU time the query took to parse, execute, and fetch the data needed to satisfy the query.

Physical I/O | This is often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user's request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at a statements' logical I/O as well.

Logical I/O | The number of memory reads the query took to satisfy the user's request. The goal of tuning I/O for a query should be to examine both logical and physical I/O, and use appropriate mechanisms to keep both to a minimum.

Repetition | The number of times the query has been executed. A problem in this area is not as easy to spot as the others unless you know your application well. A query that takes a fraction of a second to execute can be a headache on your system if it has executed erroneously (for example, a query that executes in a runaway PL/SQL loop) over and over again.

There are other criteria that you can examine like sort activity or access plan statistics (that show items like Cartesian joins and the like), but more often than not, these measures are reflected in the criteria listed above. Fortunately, Oracle records all the above measures (some only in 9i), which makes tracking the SQL that has been submitted against an Oracle database much easier.

Metrics

When you begin to look for inefficient SQL in a database, there are two primary questions you want answered:

1. What HAS been the worst SQL that has historically been run in my database?
2. What IS the worst SQL that is running right now in my database?

When troubleshooting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It could be that the query is in an inefficient PL/SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.
There is the possibility that the SQL statement just is not tuned well. You can view Performance Analyst’s Top SQL view and, if you have Embarcadero SQL Tuner installed, you can port the SQL over to SQL Tuner to better optimize the statement.

**SGA Analysis Pane**

Most DBAs know all about the Oracle System Global Area (SGA). The SGA is Oracle’s memory structural area devoted to facilitating the transfer of data and information between clients and the Oracle database. The table below describes Oracle memory structures:
<table>
<thead>
<tr>
<th>Memory Structure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default buffer cache</td>
<td>Maintains data blocks when they are read from the database. If you do not specifically place objects in another data cache, then any data requested by clients from the database is placed into this cache. The memory area is controlled by the db_cache_size parameter.</td>
</tr>
<tr>
<td>Keep buffer cache</td>
<td>You can assign various objects to a special cache that retains those object’s requested blocks in RAM for as long as the database remains up. The keep cache’s main is for often-referenced lookup tables that should be kept in memory at all times for fast access. The buffer_pool_keep parameter controls the size of this cache in Oracle8, while the db_keep_cache_size parameter handles the cache in Oracle9i or later. The keep pool is a sub-pool of the default buffer cache.</td>
</tr>
<tr>
<td>Recycle buffer cache</td>
<td>The opposite of the keep cache. When large table scans occur, the data that fills a memory cache will likely not be needed again and should be quickly discarded from RAM so that they do not occupy memory space and prevent needed blocks from assuming their place. Objects containing such data can be assigned to the recycle pool to ensure that such a thing does indeed occur. The buffer_pool_recycle parameter controls the size of this cache in Oracle8 and earlier, while the db_recycle_cache_size parameter handles the cache in Oracle9i or later.</td>
</tr>
<tr>
<td>Specific block size caches</td>
<td>You can create tablespaces whose blocksize differs from the overall database blocksize. When data is read into the SGA from these tablespaces, their data has to be placed into memory regions that can accommodate their special block size. Oracle9i or later has memory settings for 2K, 4K, 8K, 16K, and 32K caches. The configuration parameter names are in the pattern of db_nk_cache_size.</td>
</tr>
<tr>
<td>Shared pool</td>
<td>Holds object structure as well as code definitions, and other metadata. Setting the proper amount of memory in the shared pool assists a great deal in improving overall performance with respect to code execution and object references. The shared_pool_size parameter controls the memory region.</td>
</tr>
<tr>
<td>Large pool</td>
<td>You can configure an optional, specialized memory region called the large pool that holds items for shared server operations, backup and restore tasks, and other miscellaneous things. The large_pool_size parameter controls the memory region. The large pool is also used for sorting when the multi-threaded server (MTS) is implemented.</td>
</tr>
<tr>
<td>Java pool</td>
<td>Handles the memory for Java methods, class definitions, etc. The java_pool_size parameter controls the amount of memory for this area.</td>
</tr>
<tr>
<td>Redo log buffer</td>
<td>Buffers modifications that are made to the database before they are physically written to the redo log files. The log_buffer configuration parameter controls the memory area.</td>
</tr>
</tbody>
</table>

Oracle also maintains a fixed area in the SGA that contains a number of atomic variables, pointers, and other miscellaneous structures that reference areas of the SGA.
Workload Analysis Pane

It is not uncommon for one or two users to cause the majority of runtime problems that plague a database. The problem could be a runaway process, an untuned batch procedure, or other user-initiated operation. Oftentimes, user connections can get out of hand with memory consumption, and extreme cases have caused headaches at both the database and operating system level (ORA-4030 errors).

If your server does not have an overabundance of memory, periodically check to see who your heavy memory users are along with the total percentage of memory each takes up. If you see one or two users who have more than 25-50% of the total memory usage, investigate the sessions further to see the activities they are performing.

Buffer Cache Tab

The Buffer Cache tab includes the following sections:

- **Buffer Cache Hit Ratio**
- **Buffer Cache Utilization**
- **Cached Blocks by Tablespace**
- **Cached Tables**

Cached Blocks by Tablespace

Oracle’s buffer/data cache contains blocks read in from disk at the user’s request. The Cached Blocks by Tablespace section displays the amount of data held currently in the cache by tablespace.

Cached Tables

One of the ways you can help data from a table stay in the buffer/data cache as long as possible is to enable the table’s CACHE property. CACHE specifies that blocks retrieved for a table be placed at the most recently used end of the LRU list in the buffer cache when a full table scan is performed. This is particularly useful for small lookup tables.

The Cached Tables section displays the data for all tables that have their CACHE property enabled. The table below lists the information available in this section:
Memory View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>The owner of the table.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>Table Size</td>
<td>The size of the table in bytes.</td>
</tr>
</tbody>
</table>

Location  
Oracle Performance Analyst Statistics > Memory View (Oracle Performance Analyst) > Buffer Cache Tab

Metrics  
CACHE is best suited for small lookup tables. Therefore, if you see a large table that has been cached, you may want to reevaluate whether it is smart to cache the contents of that table in Oracle's buffer/data cache.

Correction  
If you wish to disable the CACHE property of a table, you can alter the table and set the property to false.

Buffer Cache Utilization

The Buffer Cache Utilization section shows the state and use of the buffers currently in the buffer cache along with a count of how many there are for each state. Typically, the statuses of the buffers are: being read, free, read and modified, and read and not modified.

Location  
Oracle Performance Analyst Statistics > Memory View (Oracle Performance Analyst) > Buffer Cache Tab

Metrics  
This grouping of statistics is quite helpful in determining if you have an overabundance of block buffers allocated. Consistently seeing large number of free buffers will clue you in to the fact that you can reduce the amount of block buffers in the cache and give memory back to the operating system. If, however, you see no free buffers within the first hour of bringing your Oracle database up, then you may consider adding more buffers to the cache.

Correction  
If a problem is found, then: Edit the Init.ora file or spfile for the database. Increase the amount of db_cache_size to a higher value if free buffers are not found (take caution to not over-allocate; ensure enough free memory exists on server before increasing value). Reduce the number of an overabundance of FREE buffers are present. Monitor new value to see if more numbers of free buffers show up for the FREE status.

Dictionary Cache Tab

Oracle's data dictionary is a component of the shared pool that contains system elements necessary for the parsing of SQL statements, security resolution, object definitions, and more.
The overall data dictionary cache hit ratio provides a key indicator in determining the performance of the shared pool, and shows how often object definitions are found in memory vs. having to read them in from disk. Because Oracle references the data dictionary many times when an SQL statement is processed, it is imperative that as much as possible of this vital reference information be kept in RAM.

The Dictionary Cache tab shows the individual elements of the data dictionary along with their associated hit ratios. In versions 6.x of Oracle, these individual elements could be tuned, but in versions 7.x and later, the only main method for tuning them involves the adjustment of the entire shared pool setting. Although not tunable from an individual parameter level, each displayed element gives insight into which area of the data dictionary is either adding to or detracting from overall performance.

The table below describes the information available on this tab:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>The name of the individual data dictionary element.</td>
</tr>
<tr>
<td>Usage</td>
<td>The number of cache entries that contain valid data.</td>
</tr>
<tr>
<td>Gets</td>
<td>The number of requests for this element.</td>
</tr>
<tr>
<td>Get Misses</td>
<td>The number of requests resulting in a cache miss.</td>
</tr>
<tr>
<td>Hit Ratio</td>
<td>The ratio of cache hits versus misses of total requests. The maximum is 100%</td>
</tr>
<tr>
<td>Scans</td>
<td>The number of scan requests.</td>
</tr>
<tr>
<td>Scan Misses</td>
<td>The number of times that a scan failed to find the needed data in the cache.</td>
</tr>
<tr>
<td>Scan Completes</td>
<td>The number of times the list was scanned completely.</td>
</tr>
<tr>
<td>Modifications</td>
<td>The number of insert, update, and delete actions.</td>
</tr>
<tr>
<td>Flushes</td>
<td>The number of disk flushes.</td>
</tr>
</tbody>
</table>

**Metrics**

An overall high data dictionary cache hit ratio is desirable, as are high hit ratios in each individual parameter. You should strive for a hit ratio between 90-100%, with 95% being a good performance benchmark.

**Note:** When a database is first started, the data dictionary cache hit ratio is not at an optimal level because all references to object definitions are relatively new, and as such, must be placed into the shared pool. Look for hit ratios between 80-90% for new database startups. If, however, after an hour or two of steady database time, the data dictionary cache hit ratio and individual hit ratios, have not increased to desirable levels, you should look into the possibility of increasing the shared_pool_size parameter.

**Note:** Databases supporting applications that involve large number of objects (such as an Oracle Financials installation) should have larger than normal shared pools to support the required object definitions.
Buffer Pools Tab

The Buffer Pools tab includes the following sections:

- Buffer Pool Hit Ratio
- Buffer Pool Memory Configuration
- Buffer Pool Object Assignments

Buffer Pool Hit Ratio

Because data objects can be referenced with different usage patterns, Oracle8 and later offers the option to intelligently place objects into one of three buffer caches. The table below describes the types of buffer caches:

<table>
<thead>
<tr>
<th>Cache</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEEP</td>
<td>Designed to minimize misses in the buffer cache. Small objects that are frequently referenced are candidates for the KEEP buffer pool.</td>
</tr>
<tr>
<td>RECYCLE</td>
<td>Designed to avoid having large numbers of infrequently accessed blocks of data crowd out objects that need to be referenced in RAM, the RECYCLE pool is good for large objects that are scanned from beginning to end without the need for keeping all their data in RAM.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>The traditional cache for all other data objects.</td>
</tr>
</tbody>
</table>

Note: Unless you specify the KEEP or RECYCLE buffer cache, Oracle automatically places objects into the DEFAULT buffer cache.

The Buffer Pool Hit Ratio section the hit ratios for each of the Oracle8 and later buffer caches so you can easily see how often the objects placed into the various caches are being referenced in memory. Examining how often data is satisfied from memory vs. disk will help you determine if the caches are large enough and if they are being used in an optimal manner. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buffer pool name</td>
<td>The name of the Oracle buffer pool.</td>
</tr>
<tr>
<td>Buffer pool hit ratio</td>
<td>The overall hit ratio for the particular cache.</td>
</tr>
</tbody>
</table>

Note: The DEFAULT buffer cache will only be shown for those installations not using the specialized caches available in Oracle8 and later.
Memory View (Oracle Performance Analyst)

Location Oracle Performance Analyst Statistics > Memory View (Oracle Performance Analyst) > Buffer Pools Tab

Metrics The KEEP buffer pool should maintain a hit ratio as close to 100% as possible. However, the buffer pool hit ratio is not near 100% until the database has been up and running in a typical state for a short time. A poor hit ratio for the RECYCLE buffer pool may not be a bad thing since there is little chance of reusing a block stored in the buffer pool before it is aged out. NOTE: If you place objects into the KEEP buffer pool, you should periodically reexamine their object sizes to ensure that they are not growing to a physical state that will jeopardize the performance of the KEEP pool.

Buffer Pool Object Assignments

Because data objects can be referenced with different types of usage patterns, Oracle8 and later offers the option to intelligently place objects into one of three buffer caches. The table below describes these three buffer caches:

<table>
<thead>
<tr>
<th>Cache</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEEP</td>
<td>Designed to minimize misses in the buffer cache. Small objects that are frequently referenced are candidates for the KEEP buffer pool.</td>
</tr>
<tr>
<td>RECYCLE</td>
<td>Designed to avoid having large numbers of infrequently accessed blocks of data crowd out objects that need to be referenced in RAM, the RECYCLE pool is good for large objects that are scanned from beginning to end without the need for keeping all their data in RAM.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>The traditional cache for all other data objects.</td>
</tr>
</tbody>
</table>

Objects not specified to go into either the KEEP or RECYCLE caches will automatically be placed into the DEFAULT buffer cache.

The Buffer Pool Object Assignments section provides a summary with respect to which types of objects have been assigned to the various buffer caches. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Type</td>
<td>The type of object (table, index, etc.).</td>
</tr>
<tr>
<td>Buffer Pool</td>
<td>The buffer cache name (KEEP, etc.).</td>
</tr>
<tr>
<td>Total Objects Assigned</td>
<td>The number of objects that have been assigned to the particular cache.</td>
</tr>
</tbody>
</table>
Metrics  When looking at overall database I/O activity, you should keep an eye out for objects that may lend themselves to being placed into a particular buffer cache. Consider using a KEEP cache for relatively small, frequently accessed tables that require fast response times. Large tables with random I/O activity and are scanned from beginning to end a lot are good candidates for a RECYCLE cache.

Buffer Pool Memory Configuration

Because data objects can be referenced with different types of usage patterns, Oracle8 and later offers the option to intelligently place objects into one of three buffer caches. The table below describes these three buffer caches:

<table>
<thead>
<tr>
<th>Cache</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEEP</td>
<td>Designed to minimize misses in the buffer cache. Small objects that are frequently referenced are candidates for the KEEP buffer pool.</td>
</tr>
<tr>
<td>RECYCLE</td>
<td>Designed to avoid having large numbers of infrequently accessed blocks of data crowd out objects that need to be referenced in RAM, the RECYCLE pool is good for large objects that are scanned from beginning to end without the need for keeping all their data in RAM.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>The traditional cache for all other data objects.</td>
</tr>
</tbody>
</table>

Objects not specified to go into either the KEEP or RECYCLE caches will automatically be placed into the DEFAULT buffer cache.
When looking at overall database I/O activity, you should keep an eye out for objects that may lend themselves to being placed into a particular buffer cache. Consider using a KEEP cache for relatively small, frequently accessed tables that require fast response times. Large tables with random I/O activity and are scanned from beginning to end a lot are good candidates for a RECYCLE cache.

Objects can be placed into different buffer pools at object creation time (using the STORAGE...BUFFER_POOL option) or existing objects can be set into a different pool with the ALTER command. Note that tables, partitions, and indexes may be placed into the different caches. If you just want to use the DEFAULT buffer pool and not enable any special caches, you can still encourage Oracle to keep certain objects in the buffer cache as long as possible using the CACHE parameter. For example, issuing the command ALTER TABLE ... CACHE specifies that the blocks retrieved for this table be placed at the most recently used end of the LRU list in the DEFAULT buffer cache when a full table scan is performed. The CACHE hint may also be used in SQL statements to cache a table, but used in this form, the blocks will only be cached until the next time the database is shut down. Once the database comes back up, the CACHE hint would have to be issued in a SQL statement again to cache the needed blocks of data.

**Latch Activity Tab**

The Latch Activity tab includes the following sections:

- **Immediate Latch Hit Ratio**
- **Latch Detail**
- **Latch Hit Ratio**
- **Latch Sleep Ratio**

**Latch Hit Ratio**

Protecting the many memory structures in Oracle’s SGA are latches. They ensure that one and only one process at a time can run or modify any memory structure at the same instant. Much more restrictive than locks (which at least allow for some collective user interaction), latches have no queuing mechanism so either you get it or you do not and are forced to continually retry. The latch hit ratio defines the number of times a process obtained a willing-to-wait.

If the latch hit ratio falls below 99%, then action should be taken to resolve the amount of latch contention occurring.
The details regarding the latch contention should be examined. Increasing the shared_pool_size can assist in latch problems also. There are a few specialized cases of latch contention that can be rectified pretty easily. The table below describes them:

<table>
<thead>
<tr>
<th>Contention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache buffer chain latch</td>
<td>This latch is responsible for protecting paths to database block buffers in the buffer cache. Very high I/O loads tend to cause contention for this latch. You can alleviate contention somewhat by adding more buffers to the cache (through the db_block_buffers/db_cache_size parameter) or by adding more LRU latch chain latches with the db_block_lru_latches parameter.</td>
</tr>
<tr>
<td>Library cache latches</td>
<td>Protects cached SQL statements in the library cache area of the Oracle shared pool. Contention for this latch is the usual result of literals being used for SQL statements instead of bind variables.</td>
</tr>
</tbody>
</table>

**Immediate Latch Hit Ratio**

Protecting the many memory structures in Oracle’s SGA are latches. They ensure that one and only one process at a time can run or modify any memory structure at the same instant. Much more restrictive than locks (which at least allow for some collective user interaction), latches have no queuing mechanism so either you get it or you do not and are forced to continually retry. The latch immediate miss ratio defines the number of times a process obtained a not-willing-to-wait latch.

Location [Oracle Performance Analyst Statistics] > Memory View (Oracle Performance Analyst) > Latch Activity Tab

Metrics If the value falls below 99%, then action should be taken to resolve the amount of latch contention occurring.

**Correction**

The details regarding the latch contention should be examined. Increasing the shared_pool_size can assist in latch problems also. There are a few specialized cases of latch contention that can be rectified pretty easily. The table below describes them:
Memory View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Contention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache buffer chain latch</td>
<td>This latch is responsible for protecting paths to database block buffers in the buffer cache. Very high I/O loads tend to cause contention for this latch. You can alleviate contention somewhat by adding more buffers to the cache (through the db_block_buffers/db_cache_size parameter) or by adding more LRU latch chain latches with the db_block_lru_latches parameter.</td>
</tr>
<tr>
<td>Library cache latches</td>
<td>Protects cached SQL statements in the library cache area of the Oracle shared pool. Contention for this latch is the usual result of literals being used for SQL statements instead of bind variables.</td>
</tr>
</tbody>
</table>

Latch Sleep Ratio

Protecting the many memory structures in Oracle’s SGA are latches. They ensure that one and only one process at a time can run or modify any memory structure at the same instant. Much more restrictive than locks (which at least allow for some collective user interaction), latches have no queuing mechanism so either you get it or you do not and are forced to continually retry.

A sleep indicates that a latch could not be obtained for a process, and that the attempt will be retried. A low ratio indicates many processes that had to sleep multiple times before obtaining a requested latch.

Location [Oracle Performance Analyst Statistics > Memory View (Oracle Performance Analyst) > Latch Activity Tab]

Metrics Sleeps should be kept as low as possible. If the overall sleep ratio falls below 99%, then action should be taken to resolve the amount of latch contention that is occurring.

Correction

The details regarding the latch contention should be examined. Increasing the shared_pool_size can assist in latch problems also. There are a few specialized cases of latch contention that can be rectified pretty easily. The table below describes them:
## Latch Detail

Protecting the many memory structures in Oracle's SGA are latches. They ensure that one and only one process at a time can run or modify any memory structure at the same instant. Much more restrictive than locks (which at least allow for some collective user interaction), latches have no queuing mechanism so either you get it or you do not and are forced to continually retry.

The Latch Detail section presents a detailed view of latch activity. The table below lists the information available:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Latch Name</td>
<td>The name of the latch.</td>
</tr>
<tr>
<td>Gets</td>
<td>The number of times the latch was requested by a process.</td>
</tr>
<tr>
<td>Misses</td>
<td>The number of failed attempts to acquire the latch on the first attempt.</td>
</tr>
<tr>
<td>Immediate Gets</td>
<td>The number of nowait requests for a latch.</td>
</tr>
<tr>
<td>Immediate Misses</td>
<td>The number of failed nowait attempts to acquire the latch on the first attempt.</td>
</tr>
<tr>
<td>Sleeps</td>
<td>The number of requests that paused while waiting for a latch.</td>
</tr>
</tbody>
</table>

Location: [Oracle Performance Analyst Statistics](#) > Memory View (Oracle Performance Analyst) > Latch Activity Tab

## Metrics

Common indicators of latch contention are a latch miss ratio (which records willing-to-wait mode latch requests) and latch immediate miss ratio (which records no-wait mode latch requests). These statistics reflect the overall health of how often latch requests were made and satisfied without waiting. If either of these exceed 1%, then latch contention may be causing system slowdowns.
There are a few latch contention situations that you can recognize and get to the bottom of quickly. The table below describes them:

<table>
<thead>
<tr>
<th>Contention Situation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache buffer chain latch</td>
<td>This latch is responsible for protecting paths to database block buffers in the buffer cache. Very high I/O loads tend to cause contention for this latch. You can alleviate contention somewhat by adding more buffers to the cache (through the db_block_buffers parameter) or by adding more LRU latch chain latches with the db_block_lru_latches parameter.</td>
</tr>
<tr>
<td>Library cache latches</td>
<td>This latch protects cached SQL statements in the library cache area of the Oracle shared pool. Contention for this latch is the usual result of literals being used for SQL statements instead of bind variables.</td>
</tr>
</tbody>
</table>

**Library Cache Tab**

The Library Cache tab includes the following sections:

- Library Cache Hit Ratio
- Library Cache Performance
- Pinned Objects

**Library Cache Performance**

The library cache holds commonly used SQL statements - basically database code objects. A method for improving performance in Oracle is to encourage the reuse of SQL statements so expensive parse operations may be avoided. The library cache assists this tuning effort.

The Library Performance sectioned tab provides insight into how efficiently the library cache is operating. The table below describes the information available in this section:
Memroy View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace</td>
<td>The region of the library cache.</td>
</tr>
<tr>
<td>Gets</td>
<td>The number of times a lock was requested for objects in the particular namespace.</td>
</tr>
<tr>
<td>Get Hit Ratio</td>
<td>The percentage of times (with 100% being the maximum) that the object was found in the cache.</td>
</tr>
<tr>
<td>Pins</td>
<td>The number of times a pin was requested for objects of this namespace.</td>
</tr>
<tr>
<td>Pin Hit Ratio</td>
<td>The percentage of times (with 100% being the maximum) that pin requests were successful.</td>
</tr>
<tr>
<td>Reloads</td>
<td>The number of times a piece of the object had to be brought back in from disk to the cache, most likely because it was flushed from the shared pool.</td>
</tr>
<tr>
<td>Invalidations</td>
<td>The number of times objects in this namespace were marked invalid because a dependent object was modified.</td>
</tr>
</tbody>
</table>

**Location**

Oracle Performance Analyst Statistics &gt; Memory View (Oracle Performance Analyst) &gt; Library Cache Tab

**Metrics**

NOTE: An overall high library cache hit ratio is a desirable thing. You should strive for a hit ratio between 95-100%, with 99% being a good performance benchmark for code reuse. When a database is first started, the library cache hit ratio, along with the individual region hit ratios, will not be at an optimal level because all code being used will be relatively new, and as such, must be parsed and placed into the shared pool. If, however, after a solid hour or two of steady database time, the library cache hit ratio has not increased to desirable levels, you should look into the possibility of increasing the shared_pool_size parameter. To keep important code objects from being aged out of the library cache, you can use the DBMS_SHARED_POOL package to pin frequently used code objects in memory so they will always be there when needed.

**Pinned Objects**

To keep important code objects from being aged out of the library cache, you can use the DBMS_SHARED_POOL package to pin frequently used code objects in memory so they will always be there when needed. The Pinned Objects section displays all objects in the library cache that have pinned. The table below lists the information available in this section:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>The user account that owns the object.</td>
</tr>
<tr>
<td>Name</td>
<td>The name of the object.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of the object: INDEX, TABLE, CLUSTER, VIEW, SET, SYNONYM, SEQUENCE, PROCEDURE, FUNCTION, PACKAGE, PACKAGE BODY, TRIGGER, CLASS, OBJECT, USER, DBLINK.</td>
</tr>
<tr>
<td>Shareable Memory</td>
<td>The amount of memory consumed by the object in the shared pool.</td>
</tr>
<tr>
<td>Loads</td>
<td>The number of times the object has been loaded into the cache. Note that this count also increases when an object has been invalidated.</td>
</tr>
<tr>
<td>Executions</td>
<td>The number of times the object has been executed by a session thread.</td>
</tr>
<tr>
<td>Locks</td>
<td>The number of users actively locking the object.</td>
</tr>
<tr>
<td>Pins</td>
<td>The number of user actively pinning the object.</td>
</tr>
<tr>
<td>Pinned?</td>
<td>Indicates (YES or NO) if this object has been pinned in memory with the DBMS_SHARED_POOL package.</td>
</tr>
</tbody>
</table>

**Shared Pool Tab**

The main components of the shared pool memory are the library and dictionary caches. Many of the caches in the shared pool increase or decrease in size automatically as necessary. The Shared Pool tab of the Memory Detail view presents the following sections:

**Shared Space Pool Utilization** - a graphical representation of the amount of used and free memory.

**Shared Pool Fragmentation** - displays the following statistics:
- Bucket: A work area defined by its optimal memory requirement.
- Free Space: The amount of free space in the bucket.
- Free Chunks: The number of free chunks that are available to be allocated from the shared pool.
- Average Size: The average size of a chunk.
- Largest: The size of the largest chunk.

**Shared Pool Usage** - The Shared Pool Usage section shows the following statistics:
- Shared Pool Component Name
- Amount Used (bytes)
PGA Tab

The PGA tab displays statistical measures and techniques that let you manage a session's Program Global Area.

**Note:** This information is available for Oracle9i and later.

The PGA tab includes the following sections:

- PGA Overview
- PGA Workarea Summary
- PGA Session Detail

For more information, see *Memory View (Oracle Performance Analyst)*.

**PGA Overview**

Oracle's Program Global Area (PGA) is a private memory region containing data and control information for every connected process. Examples of PGA information are the runtime area of a cursor and memory sort space. If shared servers are used, then part of the runtime area can be located in the SGA.

Intensive queries cause a big portion of the PGA to be dedicated to work areas supporting memory intensive operators, such as the following:

- Sort-based operators (for example, ORDER BY, GROUP BY, ROLLUP, window functions)
- Hash-join
- Bitmap merge
- Bitmap create
- Write buffers used by bulk load operations

A sort operator uses a sort area to perform the in-memory sort of a set of rows. Similarly, a hash-join operator uses a hash area to build a hash table.

**Note:** This information is available for Oracle9i and later.
Memory View (Oracle Performance Analyst)

Location Oracle Performance Analyst Statistics > Memory View (Oracle Performance Analyst) > PGA Tab

Metrics The size of a PGA area can be controlled and tuned. Larger work areas can significantly improve performance of session work, with the trade off being higher memory consumption. The size of a session’s PGA should be big enough so that it can accommodate the input data and auxiliary memory structures allocated by its requested SQL actions. This is known as the optimal size of a PGA work area. When the size of a PGA work area is smaller than optimal, the response time increases, because an extra pass is performed over part of the input data. This is known as the one-pass size of the PGA work area. Under the one-pass threshold, when the size of a work area is smaller than its input data size, multiple passes over the input data are needed. This could drastically increase the response time of the session. This is known as the multi-pass size of the work area. The goal is to have most work areas running with an optimal size (more than 90% or more for OLTP systems), while a smaller amount are running with a one-pass size (less than 10%). Multi-pass execution should be completely avoided. Prior to Oracle9i, the PGA was controlled using the SORT_AREA_SIZE, HASH_AREA_SIZE, BITMAP_MERGE_AREA_SIZE and CREATE_BITMAP_AREA_SIZE parameters. Setting these parameters is difficult, because the maximum PGA size is ideally selected based on data input size and total number of work areas active in the system. These two factors vary from one work area to another and from one point in time to another.

Correction

With Oracle9i, you can simplify and improve the way PGA memory is allocated, by enabling automatic PGA memory management. In this mode, Oracle dynamically adjusts the size of the portion of the PGA memory dedicated to work areas, based on an overall PGA memory target explicitly set by the DBA. To enable automatic PGA memory management, you have to set the initialization parameter PGA_AGGREGATE_TARGET.

The table below describes two metrics you should to watch:
Memory View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Over allocation count</td>
<td>Over-allocating PGA memory can happen if the value of PGA_AGGREGATE_TARGET is too small to accommodate the PGA other component in the previous equation plus the minimum memory required to execute the work area workload. When this happens, Oracle cannot honor the initialization parameter PGA_AGGREGATE_TARGET, and extra PGA memory needs to be allocated. If over-allocation occurs, you should increase the value of PGA_AGGREGATE_TARGET.</td>
</tr>
<tr>
<td>Cache hit percentage</td>
<td>This metric is computed by Oracle to reflect the performance of the PGA memory component. A value of 100% means that all work areas executed by the system since instance start-up have used an optimal amount of PGA memory. When a work area cannot run optimally, one or more extra passes is performed over the input data. This reduces the cache hit percentage in proportion to the size of the input data and the number of extra passes performed.</td>
</tr>
</tbody>
</table>

PGA Workarea Summary

Oracle’s Program Global Area (PGA) is a private memory region containing data and control information for every connected process. Examples of PGA information are the runtime area of a cursor and memory sort space. If shared servers are used, then part of the runtime area can be located in the SGA.

Intensive queries cause a big portion of the PGA to be dedicated to work areas supporting memory intensive operators, such as the following:

- Sort-based operators (for example, ORDER BY, GROUP BY, ROLLUP, window functions)
- Hash-join
- Bitmap merge
- Bitmap create
- Write buffers used by bulk load operations

A sort operator uses a sort area to perform the in-memory sort of a set of rows. Similarly, a hash-join operator uses a hash area to build a hash table.

**Note:** This information is available for Oracle9i and later.
Memory View (Oracle Performance Analyst)

Location  Oracle Performance Analyst Statistics > Memory View (Oracle Performance Analyst) > PGA Tab

Metrics  The size of a PGA area can be controlled and tuned. Larger work areas can significantly improve performance of session work, with the trade off being higher memory consumption. The size of a session’s PGA should be big enough so that it can accommodate the input data and auxiliary memory structures allocated by its requested SQL actions. This is known as the optimal size of a PGA work area. When the size of a PGA work area is smaller than optimal, the response time increases, because an extra pass is performed over part of the input data. This is known as the one-pass size of the PGA work area. Under the one-pass threshold, when the size of a work area is smaller than its input data size, multiple passes over the input data are needed. This could drastically increase the response time of the session. This is known as the multi-pass size of the work area. The goal is to have most work areas running with an optimal size (more than 90% or more for OLTP systems), while a smaller amount are running with a one-pass size (less than 10%). Multi-pass execution should be completely avoided. Prior to Oracle9i, the PGA was controlled using the SORT_AREA_SIZE, HASH_AREA_SIZE, BITMAP_MERGE_AREA_SIZE and CREATE_BITMAP_AREA_SIZE parameters. Setting these parameters is difficult, because the maximum PGA size is ideally selected based on data input size and total number of work areas active in the system. These two factors vary a lot from one work area to another and from one point in time to another.

Correction  With Oracle9i, you can simplify and improve the way PGA memory is allocated, by enabling automatic PGA memory management. **Location** [Oracle Performance Analyst Statistics](#) > Memory View (Oracle Performance Analyst) > PGA Tab
I/O View (Oracle Performance Analyst)

In addition to a Home page, the I/O category of Oracle Performance Analyst includes the following tabbed pages:

- Access Pattern Detail Tab
- Datafile I/O Tab
- Job Queue Activity Tab
- DBWR/LGWR Tab
- Rollback I/O Tab
- Sort Activity Tab
- Table I/O Tab

Home

The I/O Home page includes the following sections:

- Key Systems Analysis Pane
- Bottleneck Analysis Pane
- I/O Access Patterns - I/O
- SQL Analysis Pane
- Workload Analysis Pane

Key Systems Analysis Pane

When complaints begin to surface about your database’s performance, oftentimes the root cause can be traced to one or more issues with I/O. The thing to keep in mind when you begin to monitor the I/O of your database is that you are actually reviewing the success of your physical design model.

All the physical storage characteristics and placements, the table and index designs, and the speed with which it all works are on display when I/O is monitored. Because a database’s main index of performance is measured by how fast I/O needs are satisfied, it is your responsibility to quickly interrogate Oracle to determine if a reported database slowdown is I/O related.

Physical I/O

Physical I/O consists of Oracle going to disk to gather or write data. The database writer (DBWR) and log writer (LGWR) processes typically perform all the I/O work in the database. You can also use other processes like the checkpoint and archive processes.
Embarcadero Performance Analyst shows three key indicators of physical I/O. The table below describes these indicators:

<table>
<thead>
<tr>
<th>Indicator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical Reads</td>
<td>Physical Reads is the total number of physical reads performed on all datafiles since the last refresh.</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>Physical Writes is the total number of times the DBWR process has performed writes to various database datafiles since the last refresh.</td>
</tr>
<tr>
<td>Redo Writes</td>
<td>Oracle's redo logs are hotbeds of I/O activity in databases that store heavily modified data. Redo log files are used to perform database recovery in the event of a system crash. Redo logs are written to in a cyclical fashion - each log file is filled up before Oracle moves on to the next file. The redo writes statistic reflects the total number of redo writes by the LGWR process since the last refresh.</td>
</tr>
</tbody>
</table>

Metrics

The table below describes metrics for Physical I/O statistics:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical Reads</td>
<td>Large numbers of physical reads could reflect a too small data/buffer cache. The Buffer Cache Hit Ratio is a better indicator of overall logical vs. physical I/O.</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>Wait events related to I/O activity are good indicators of physical I/O problems. These events include db file parallel write and db file single write.</td>
</tr>
</tbody>
</table>

Correction

Doing the following can negate large numbers of continuous physical reads:

- Increasing the size of the data/buffer cache.
- Pinning often-referenced objects in memory by using the KEEP buffer pool.
- Placing heavily scanned objects in larger blocksize tablespaces (16-32KB). For Oracle9i or later.
- Tune SQL statements for better efficiency.

Logical I/O

Logical I/O refers to data access performed in memory. The database writer (DBWR) and log writer (LGWR) processes typically perform all the I/O work in the database. You can also use other processes like the checkpoint and archive processes (CKPT and ARCH). Embarcadero Performance Analyst shows three key indicators of logical I/O. The table below describes these indicators:
## I/O View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Indicator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logical Reads</td>
<td>Logical Reads is the total number of db block gets and consistent gets (data read from memory) since the last refresh.</td>
</tr>
<tr>
<td>Logical Changes</td>
<td>Logical Changes is the total number of changes that were made to all blocks in the SGA that were part of an update or delete operation. These changes generate redo log entries and are permanent if the transaction is committed. The number of logical changes is an approximate indication of total database work.</td>
</tr>
<tr>
<td>Consistent Reads</td>
<td>Consistent Reads is the total number of times a consistent read was requested for a database block. Such a read is performed from Oracle’s rollback segments.</td>
</tr>
</tbody>
</table>

### Metrics

Regarding raw logical I/O counts, no hard-core metrics exist. However, because physical I/O takes longer to complete than logical (memory) I/O, you should minimize physical read operations when possible. The Buffer Cache Hit Ratio is a better indicator of overall logical vs. physical I/O.

### Correction

While logical I/O is still up to 1,400 times faster than physical disk access, it would be wise to investigate the top logical I/O process using Performance Analyst and see what SQL it is executing. If one process on the system is consuming between 25-50% of the overall amount, their SQL might require tuning.

## Bottleneck Analysis Pane

When an Oracle database is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting can mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. You can use Bottleneck Analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps you track where a database has been spending its time. If heavy table scan activity has been dragging a database’s performance down, you can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, you can discover a fair amount of detail about which sessions and objects are causing the problem.

For wait event analysis to be properly carried out, it is imperative that the timed_statistics initialization parameter be set to TRUE. By default this parameter is set to FALSE, which disallows the collection of wait times for each wait event defined to the Oracle engine. For one to really understand the impact of wait events on database performance, you need to not only discover what the database is or has been waiting on, but the durations of the waits. Having both allows a complete picture to be formed regarding the magnitude of wait-initiated performance degradations. Almost all Oracle experts now agree that allowing the collection of timing statistics adds little if anything to database overhead, so setting timed_statistics to TRUE should not be a worry. The
Performance Analyst I/O home page identifies the top database and log file waits that can cause decreased performance.

The Bottleneck Analysis section includes:

- **Hottest Database Files**
- **Top Database File Waits**
- **Top Log File Waits**

### Hottest Database Files

The Hottest Database Files section lists the most active database files as indicated by physical I/O activity.

**Location**  
Oracle Performance Analyst Statistics > I/O View (Oracle Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  
Understanding the storage-level hot spots of a database is beneficial for a couple of reasons. First, you can get a feel for overworked physical disks by viewing I/O statistics at the tablespace and datafile levels. If a particular disk or set of disks is under too much strain, you can relocate the tablespaces to other less-used devices or create new tablespaces on different disks and move hot objects to them (assuming, of course, you have extra disks available). Second, if you have used standard DBA practice and placed indexes in their own tablespace, you can view the I/O statistics for that tablespace and see if the indexes are actually being used.

**Correction**  
Here are some areas to consider when viewing Hottest Database Files: Seeing much activity in the SYSTEM tablespace and datafiles can indicate recursive calls (space management, etc.). The use of locally-managed tablespaces can help with space management as it relates to data dictionary references. Temporary tablespaces (devoted to sort activity) showing higher volumes of physical I/O could indicate a problem with excessive disk sorts. You might want to quickly review all the physical I/O for each drive/file system and get a feel for the overworked disks on your server. If you have under utilized disk drives (with their own controllers), consider relocating some tablespaces that exhibit high I/O characteristics to those drives.

### Top Database File Waits

When viewing wait statistics, there are many levels of detail. The first level is the system view, which provides a global, cumulative snapshot of all the waits that have occurred on a system. The Top Database File Waits section filters all system wait events to present waits that are associated with database file activity. It ranks the top events by the count of total waits.
Correction Oracle documentation contains a listing and description of every current wait event defined in Oracle. DBAs unfamiliar with what each event represents should keep this listing close by as they examine wait-based event metrics. The most common database file wait is a db file scattered read, which indicates table scan activity. Small table scans are normally not a problem as Oracle can access data from small tables by quickly caching and scanning them. Scans of large tables can be confirmed by examining the I/O access pattern metrics on the Performance Analyst I/O home page. Information is also available on which sessions are causing the large table scans. Finally, one thing to watch is not only the actual waits, but also the wait time in seconds. If no wait time is observed with each wait type, then performance is likely not endangered by the event.

**Top Log File Waits**

When viewing wait statistics, there are many levels of detail. The first level is the system view, which provides a global, cumulative snapshot of all the waits that have occurred on a system. This section filters all system wait events to present waits that are associated with log file activity. It ranks the top events by the count of total waits.

Correction Oracle documentation contains a listing and description of every current wait event defined in Oracle. DBAs unfamiliar with what each event represents should keep this listing close by as they examine wait-based event metrics. The most common database file wait is a log file parallel write, which indicates how quickly Oracle can flush the log buffer. Excessive wait times associated with this event count indicate a bottleneck at the log buffer level. Finally, one thing to watch is not only the actual waits, but also the wait time in seconds. If no wait time is observed with each wait type, then performance is likely not endangered by the event.

**SQL Analysis Pane**

Much of a database's overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end user response times. SQL statements that use much memory can also cause a problem in a database.

Before you can identify problem SQL in your database, you have to ask the question, “What is bad SQL?” What criteria do you use when you begin the hunt for problem SQL in your critical systems? Even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every Oracle professional's satisfaction. The SQL Analysis for I/O shows what SQL statements have consumed the largest percentages of physical and logical I/O, sort activity, and rows processed. The table below lists some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:
## I/O View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overall Response (Elapsed Time)</td>
<td>The amount of time the query took to parse, execute, and fetch the data needed to satisfy the query. It should not include the network time needed to make the round trip from the requesting client workstation to the database server. This statistic is available in Oracle9i or later.</td>
</tr>
<tr>
<td>CPU Time</td>
<td>The amount of CPU time the query took to parse, execute, and fetch the data needed to satisfy the query.</td>
</tr>
<tr>
<td>Physical I/O</td>
<td>This is often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user's request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at a statements' logical I/O as well.</td>
</tr>
<tr>
<td>Logical I/O</td>
<td>This is a measure of how many memory reads the query took to satisfy the user's request. The goal of tuning I/O for a query should be to examine both logical and physical I/O, and use appropriate mechanisms to keep both to a minimum.</td>
</tr>
<tr>
<td>Repetition</td>
<td>This is a measure of how often the query has been executed. A problem in this area is not as easy to spot as the others unless you know your application well. A query that takes a fraction of a second to execute may still be causing a headache on your system if it has executed erroneously (for example, a query that executes in a runaway PL/SQL loop) over and over again.</td>
</tr>
</tbody>
</table>

There are other criteria that you can examine like sort activity or access plan statistics (that show items like Cartesian joins and the like), but more often than not, these measures are reflected in the criteria listed above. Fortunately, Oracle records all the above measures (some only in 9i), which makes tracking the SQL that has been submitted against an Oracle database much easier.
Metrics When you begin to look for inefficient SQL in a database, there are two primary questions you want answered: What HAS been the worst SQL that has historically been run in my database? What IS the worst SQL that is running right now in my database? When troubleshooting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It could be that the query is in an inefficient PL/SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.

There is the possibility that the SQL statement just is not tuned well. To determine that, you can go further into Performance Analyst's Top SQL view and, if you have Embarcadero SQL Tuner installed, you can port the SQL over to SQL Tuner to better optimize the statement.

I/O Access Patterns - I/O

There are many different routes that Oracle can take to access various objects contained in a database. The I/O Access Patterns section summarizes the methods Oracle is using to satisfy end-user requests for data.

Location Oracle Performance Analyst Statistics > I/O View (Oracle Performance Analyst) > Home > SQL Analysis Pane

Metrics Long table scans are typically an activity to avoid as they have the capability to cause needless physical and logical I/O as well as flood the buffer cache with seldom referenced blocks of data. You can discover which sessions have been causing the most large table scans. The table fetch continued row statistic is indicative of chained/migrated row I/O. Such activity is not desired because chained/migrated row access can cause twice the I/O needed to access a table. Oracle must pick do two or more I/Os to read a chained/migrated row in a table. You can discover which sessions have been accessing tables with chained/migrated rows.

Workload Analysis Pane

It is not uncommon for one or two users to cause the majority of runtime problems that plague a database. The problem could be a runaway process, an untuned batch procedure, or other user-initiated operation. The Top I/O Hogs table shows the top sessions that have caused the most physical I/O on the system (both reads and writes).

Metrics If you see one or two users who have caused more than 25-50% of the total memory usage, go further into the sessions to see the activities they are performing.

I/O Tablespace Tab

Physical I/O consists of Oracle going to disk to gather or write data. Logical I/O refers to data access performed in memory. The database writer (DBWR) and log writer (LGWR) processes typically perform all the I/O work in the database. Other processes like the checkpoint and archive processes (CKPT and ARCH) may also be used.
The Tablespace I/O tab displays details concerning the physical I/O activity at the tablespace level. The table below lists the information available on this tab:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace Name</td>
<td>The name of the tablespace.</td>
</tr>
<tr>
<td>Physical Reads</td>
<td>The cumulative number of physical reads.</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>The cumulative number of physical writes.</td>
</tr>
<tr>
<td>Physical Block Reads</td>
<td>The cumulative number of physical block reads.</td>
</tr>
<tr>
<td>Physical Block Writes</td>
<td>The cumulative number of physical block writes.</td>
</tr>
<tr>
<td>Physical Read Time</td>
<td>The time spent reading from the tablespace (in hundredths of seconds).</td>
</tr>
<tr>
<td>Physical Write Time</td>
<td>The time spent writing to the tablespace (in hundredths of seconds).</td>
</tr>
</tbody>
</table>

Metrics Generally, you want to see much more logical I/O activity than physical I/O, at least with respect to reads, although this in and of itself is a guarantee of good I/O performance. Seeing logical and physical reads keeping pace with one another is a sure sign that the Oracle SGA’s buffer cache is sized too small or that needless, large table scans are occurring, which cause blocks of data to be continually read in and flushed out of the buffer cache. Other telltale signs of trouble brewing are large amounts of activity visible in user’s TEMP tablespaces. The normal interpretation of such a thing is that a large number of disk sorts are taking place (perhaps because the Init.ora/spfile parameter SORT_AREA_SIZE may be set too small).

**Datafile I/O Tab**

Physical I/O consists of Oracle going to disk to gather or write data. Logical I/O refers to data access performed in memory. The database writer (DBWR) and log writer (LGWR) processes typically perform all the I/O work in the database against the physical datafile used to hold information. The checkpoint and archive processes (CKPT and ARCH), also perform I/O work in the database.

The Datafile I/O tab displays details concerning the physical I/O activity at the datafile level. The table below lists the information available on this tab:
### Column

<table>
<thead>
<tr>
<th>DataFile Name</th>
<th>The name of the datafile.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace Name</td>
<td>The name of the tablespace.</td>
</tr>
<tr>
<td>Physical Reads</td>
<td>The cumulative number of physical reads.</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>The cumulative number of physical writes.</td>
</tr>
<tr>
<td>Block Reads</td>
<td>The cumulative number of physical block reads.</td>
</tr>
<tr>
<td>Block Writes</td>
<td>The cumulative number of physical block writes.</td>
</tr>
<tr>
<td>Read Time</td>
<td>The time spent reading from the tablespace (in hundredths of seconds).</td>
</tr>
<tr>
<td>Write Time</td>
<td>The time spent writing to the tablespace (in hundredths of seconds).</td>
</tr>
</tbody>
</table>

### Metrics

Generally, you will want to see much more logical I/O activity than physical I/O, at least with respect to reads, although this in and of itself is a guarantee of good I/O performance. Seeing logical and physical reads keeping pace with one another is a sure sign that the Oracle SGA’s buffer cache is sized too small or that needless, large table scans are occurring, which cause blocks of data to be continually read in and flushed out of the buffer cache. Other telltale signs of trouble brewing are large amounts of activity visible in user’s TEMP tablespaces. The normal interpretation of such a thing is that a large number of disk sorts are taking place (perhaps because the `init.ora/spfile` parameter `SORT_AREA_SIZE` may be set too small). This view also allows you to see the ‘hot’ files in terms of physical I/O activity. Seeing too much activity on one drive/file system may indicate a need for better file striping.

### Rollback I/O Tab

The Rollback I/O tab includes the following sections:

- [Active Rollback Details](#)
- [Rollback I/O](#)
- [Session Rollback Activity](#)

For more information, see [Home](#).

### Rollback I/O

To undo changes made to the Oracle database from within a transaction, Oracle writes data to individual rollback segments. Oracle also uses these segments to maintain read consistency for multiple users of data that is being modified. Because Oracle reads from and writes data to rollback segments, they can become very hot areas for I/O.
The Rollback I/O section presents everything necessary to view and troubleshoot rollback problems. The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the rollback segment.</td>
</tr>
<tr>
<td>Size</td>
<td>The size of the rollback segment in KBs.</td>
</tr>
<tr>
<td>Shrinks</td>
<td>The number of times the rollback segment has decreased in size.</td>
</tr>
<tr>
<td>Extents</td>
<td>The number of times the rollback segment has increased in size.</td>
</tr>
<tr>
<td>Gets</td>
<td>The number of header gets (the segment has been used).</td>
</tr>
<tr>
<td>Waits</td>
<td>The number of header waits.</td>
</tr>
<tr>
<td>Writes</td>
<td>The number of bytes written to the rollback segment.</td>
</tr>
<tr>
<td>Active Trans</td>
<td>Indicates whether the rollback segment is active (non zero) or not (zero value).</td>
</tr>
<tr>
<td>Status</td>
<td>Indicates the status of the rollback segment, with the two main results being OFFLINE (a segment is offline and unavailable for transactions) and ONLINE (a rollback segment is online and available for transactional use).</td>
</tr>
<tr>
<td>High Water Mark</td>
<td>The largest size that the rollback segment has ever grown to.</td>
</tr>
</tbody>
</table>
Metrics

To properly tune rollback I/O, you must first make sure that you have enough segments to accommodate the workload of the database. Constantly seeing a count of active rollback segments equal to or near the number of rollbacks defined for the database is an indicator that you should create more. An overall rollback contention ratio of 1% or greater is an indicator of too few rollbacks. Seeing wait counts greater than zero for each rollback segment is further evidence that you should create more rollback segments. Oracle9i provides the UNDO tablespace to automatically generate and eliminate the ‘correct’ number of rollback segments for a system given a certain workload. After ensuring that enough rollback segments exist in the database, you should then turn your attention to the question of sizing. Dynamic rollback extension can take a toll on performance when rollback segments are consistently enlarged to accommodate heavy transaction loads. Seeing rollback segments undergoing numerous extends and shrinks (as Oracle returns a segment back to its OPTIMAL setting), as well as rollback segments having current or high-water mark sizes greater than their OPTIMAL setting usually is a good indicator that they should be permanently enlarged. Again, Oracle9i’s automatic undo management can assist in this process.

Active Rollback Details

Rollback or undo segments are used to guarantee transactional integrity. When a transaction has not been committed or rolled back, a rollback segment will be in use with live transactional data. The Active Rollback Details section displays information concerning active rollback segments. The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SID</td>
<td>The system ID of the session using the rollback segment.</td>
</tr>
<tr>
<td>Username</td>
<td>The account/schema name of the session.</td>
</tr>
<tr>
<td>Rollback</td>
<td>The rollback segment name containing the session’s transaction.</td>
</tr>
<tr>
<td>Start Time</td>
<td>The time the transaction was initiated.</td>
</tr>
<tr>
<td>Blocks Used</td>
<td>The number of rollback blocks used by the transaction.</td>
</tr>
</tbody>
</table>

Location

Oracle Performance Analyst Statistics > I/O View (Oracle Performance Analyst) > Rollback I/O Tab

Metrics

Seeing transactions with dated start times may indicate transactions that are the source of lock contention.

Session Rollback Activity

For all connected sessions, Oracle maintains statistics regarding each session’s counts of rollbacks and commits. The Session Rollback Activity section displays a transactional
summary/history that helps identify sessions with excessive rollback activity. The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SID</td>
<td>The system ID of the session.</td>
</tr>
<tr>
<td>Username</td>
<td>The account/schema name of the session.</td>
</tr>
<tr>
<td>Machine Name</td>
<td>The machine name where the session logged on.</td>
</tr>
<tr>
<td>Logon Time</td>
<td>The time the session logged into Oracle.</td>
</tr>
<tr>
<td>User Rollbacks</td>
<td>The number of times the user manually issued the ROLLBACK statement or an error occurred during the user’s transaction.</td>
</tr>
<tr>
<td>Transactions Rolled Back</td>
<td>The number of transactions successfully rolled back.</td>
</tr>
<tr>
<td>User Commits</td>
<td>The number of times a user transaction was committed.</td>
</tr>
</tbody>
</table>

Location: [Oracle Performance Analyst Statistics](#) > I/O View (Oracle Performance Analyst) > Rollback I/O Tab

Metrics: Seeing high numbers of transactions rolled back might indicate an application error or other transactional problem.

**DBWR/LGWR Tab**

The DBWR/LGWR tab includes the following sections:

- Daily Archive Log Summary (Last 7 Days)
- Database Writer Detail
- Log Writer Detail
- Redo Wastage
- Table I/O Tab

**Database Writer Detail**

The database writer process (DBWR) handles the flow of information from Oracle’s physical datafiles to and from the various memory structures in the system global area (SGA). On platforms that support it, you can configure and use multiple DBWR processes. The log writer (LGWR) process manages the information contained in Oracle's online redo log files and redo log buffer area. The table below lists the information available in this section:
### Log Writer Detail

The database writer process (DBWR) handles the flow of information from Oracle’s physical datafiles to and from the various memory structures in the system global area (SGA). On platforms that support it, you can configure and use multiple DBWR processes. The log writer (LGWR) process manages the information contained in Oracle’s online redo log files and redo log buffer area. The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statistic</td>
<td>The specific metric for the log writer.</td>
</tr>
<tr>
<td>Amount</td>
<td>The value for the statistic.</td>
</tr>
</tbody>
</table>

### Daily Archive Log Summary (Last 7 Days)

To allow for point-in-time recovery, Oracle writes copies of redo log information to disk. When a database is running in archive log mode, a DBA can (with proper backup techniques in place) recovery nicely from a database error and roll forward to almost any point in time needed, as long as the proper archive logs are in place.
The I/O needed to write these archive logs is handled by Oracle’s ARCH process. The Daily Archive Log Summary shows the number of archive logs written each day for the past seven days.

Location Oracle Performance Analyst Statistics > I/O View (Oracle Performance Analyst) > DBWR/LGWR Tab

Metrics Heavy redo log activity can lead to many archive files being written out to disk. Batch jobs have the potential to move very fast - sometimes so fast that the online redo logs wrap back around before they have a chance to be archived. Messages of this nature will oftentimes show up in the Oracle alert log. If this is the case, you may want to think about increasing the size of the online redo log files, or increase the number of redo logs in general. Seeing archive files written more than one per hour or half-hour may indicate a too small redo size (or above average data modification load). If archive log protection is a concern (in other words, you do not want to lose an archive file that may be needed for recovery) and you are using Oracle8, you can now take advantage of the feature to write archive files to more than one destination on disk. It also allows multiple ARCH processes to now be invoked. Investigate the use of the Init.ora parameters log_archive_dest_n and log_archive_max_processes. Always remember one thing with respect to archive files and running Oracle in archive log mode: running out of archive file space on the server is a sure fire way to halt all activity in a database. Make sure you have plenty of free space available on your archive drives. Also, implement a purge procedure for older archives in conjunction with a good backup routine.

Redo Wastage

Oracle's redo logs are hotbeds of I/O activity in databases that store heavily modified data. Redo log files are used to perform database recovery in the event of a system crash. Redo logs are written to in a cyclical fashion - each log file is filled up before Oracle moves on to the next file. The Redo Wastage section shows how many bytes were wasted by redo log buffers being written before they were full.

Location Oracle Performance Analyst Statistics > I/O View (Oracle Performance Analyst) > DBWR/LGWR Tab

Metrics Viewing a high percentage of wasted bytes to overall redo bytes can help you identify if redo wastage is a problem on your system.

Correction Sometimes heavy redo wastage occurs when the log_checkpoint_interval parameter is set too high. If you think this is the case for your system, then Edit the Init.ora file for the database. Change the amount of log_checkpoint_interval to a lower value. Cycle the Oracle server when possible to allow the new value to take effect. Monitor new value to see if performance improves.

Table I/O Tab

I/O activity at the table level has historically been difficult to get with Oracle. Oracle9i and later contain better dictionary elements to help get a clearer picture of table I/O, but earlier versions of Oracle allow an estimation only. The table below lists the information available in the Estimated Physical I/O by table on this tab:
The Sort Activity tab includes the following sections:

- **Current Disk Sorts**
- **Session Sort Detail**

### Session Sort Detail

Excessive sort activity can degrade a user's or overall database performance. When a sort operation occurs, Oracle attempts to perform the sort in a memory space, assigned by the DBA, which exists at the operating system level. If the sort is too large to be contained within this space, it will continue the sort on disk - specifically, in the user's assigned temporary tablespace.

The Session Sort Detail section displays historical sort statistics for every logged on session. The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SID</td>
<td>The unique identified given the session by Oracle.</td>
</tr>
<tr>
<td>Username</td>
<td>The user account a session is using.</td>
</tr>
<tr>
<td>Machine Name</td>
<td>The machine name where the session logged on.</td>
</tr>
<tr>
<td>Logon Time</td>
<td>The time the session logged into Oracle.</td>
</tr>
<tr>
<td>Disk Sorts</td>
<td>The cumulative number of disk sorts for the session.</td>
</tr>
<tr>
<td>Memory Sorts</td>
<td>The cumulative number of memory sorts for the session.</td>
</tr>
<tr>
<td>Row Sorted</td>
<td>The cumulative number of rows sorted by the session.</td>
</tr>
<tr>
<td>Disk/Memory Sort Ratio</td>
<td>The percentage of times the session had to perform a disk sort.</td>
</tr>
</tbody>
</table>
Sort Activity Tab

Metrics

Techniques to include in your overall performance strategy are those that relate to minimizing the amount of sort activity overall and specifically sort activity that takes place on disk. A good place to start is by understanding things that cause sorts in the first place. A list of sort-related commands and SQL-related options include CREATE INDEX, ALTER INDEX ... REBUILD, DISTINCT, ORDER BY, GROUP BY, UNION, INTERSECT, MINUS, IN, and NOT IN, as well as certain unindexed joins and certain correlated subqueries. All of these SQL commands have the potential to create a sort. As a DBA, you probably will not know which queries will have their sorts performed entirely in memory and which ones will be forced to go to disk. There are times you simply cannot stop disk sort activity (such as in data warehousing environments). That being the case, you should ensure the following are true in your database: Your users' TEMPORARY TABLESPACE assignment is not the SYSTEM tablespace, which is the default assignment. The TEMPORARY TABLESPACE assigned to your users is placed on a fast disk. The TEMPORARY TABLESPACE has the tablespace parameter TEMPORARY assigned to it, which allows sort activity to be performed in a more efficient manner. If your overall memory sort ratio falls below 90%, you may want to increase the parameters devoted to memory sorts - sort_area_size and sort_area_retained_size. Keep in mind that individual users might have the ability to alter their own sessions and increase their sort_area_size assignments! As a DBA, you may want to restrict users that have the ALTER SESSION privilege. In addition to increasing the amount of memory devoted to sorting, you should also hunt down inefficient SQL that cause needless sorts. For example, UNION ALL does not cause a sort whereas UNION does in an SQL query (to eliminate duplicate rows). DISTINCT oftentimes is coded inappropriately (especially by folks transferring from Microsoft Access, which used to use DISTINCT for nearly every SELECT query).

Current Disk Sorts

Excessive sort activity – especially disk sorts - can degrade a user’s or overall database performance. When a sort operation occurs, Oracle attempts to perform the sort in a memory space, assigned by the DBA, which exists at the operating system level. If the sort is too large to be contained within this space, it will continue the sort on disk - specifically, in the user’s assigned TEMPORARY TABLESPACE.

The Current Disk Sorts section displays sort statistics for every session currently performing a disk sort. The table below lists the information available in this section:
### I/O View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Text</td>
<td>The SQL statement causing the disk sort.</td>
</tr>
<tr>
<td>SID</td>
<td>The unique identified given the session by Oracle.</td>
</tr>
<tr>
<td>Username</td>
<td>The user account a session is using.</td>
</tr>
<tr>
<td>Machine Name</td>
<td>The machine name where the session logged on.</td>
</tr>
<tr>
<td>Tablespace</td>
<td>The tablespace containing the sort segments used by the sort.</td>
</tr>
<tr>
<td>Extents</td>
<td>The number of extents being used for the sort.</td>
</tr>
<tr>
<td>Blocks</td>
<td>The number of blocks being used for the sort.</td>
</tr>
</tbody>
</table>

**Location**  
Oracle Performance Analyst Statistics > I/O View (Oracle Performance Analyst) > Sort Activity Tab

**Metrics**

### Job Queue Activity Tab

The Job Queue Activity tab includes the following sections:

- Job Queue Summary
Job Queue Summary

Oracle provides a way for Oracle developers to submit and run jobs through the job queue feature of the Oracle database. The table below lists the information available on this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total Jobs</td>
<td>The number of jobs defined to the database.</td>
</tr>
<tr>
<td>Broken</td>
<td>The number of jobs broken (disabled).</td>
</tr>
<tr>
<td>Failures</td>
<td>The number of job failures.</td>
</tr>
<tr>
<td>Running</td>
<td>The number of jobs currently running.</td>
</tr>
</tbody>
</table>

Problem Jobs

Oracle provides a way for Oracle developers to submit and run jobs through the job queue feature of the Oracle database. Sometimes a job may fail or become disabled (broken). The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Job ID</td>
<td>The job number for the job.</td>
</tr>
<tr>
<td>Login User</td>
<td>The user account used to run the job.</td>
</tr>
<tr>
<td>Last Date Successfully Run</td>
<td>The date/time of when the job last successfully ran.</td>
</tr>
<tr>
<td>Broken</td>
<td>Indicates if the job is disabled or not.</td>
</tr>
<tr>
<td>Failures</td>
<td>The number of failures the job has experienced.</td>
</tr>
</tbody>
</table>

Location: Oracle Performance Analyst Statistics > I/O View (Oracle Performance Analyst) > Job Queue Activity Tab

Running Jobs Detail

Oracle provides a way for Oracle developers to submit and run jobs through the job queue feature of the Oracle database. The Running Jobs Detail section provides information about currently running jobs. The table below lists the information available in this section:
I/O View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SID</td>
<td>The unique identifier given the session by Oracle.</td>
</tr>
<tr>
<td>Job ID</td>
<td>The job number for the job.</td>
</tr>
<tr>
<td>Start Date/Time</td>
<td>Indicates when the job started.</td>
</tr>
<tr>
<td>Submitted by</td>
<td>Indicates the session that submitted the job.</td>
</tr>
<tr>
<td>Run As</td>
<td>Indicates which account is used to run the job.</td>
</tr>
<tr>
<td>Parse As</td>
<td>Indicates which account is used to parse the job.</td>
</tr>
<tr>
<td>Next Run Date/Time</td>
<td>Indicates when the job will next run.</td>
</tr>
<tr>
<td>Job Contents</td>
<td>Indicates the actual command used by the job.</td>
</tr>

Access Pattern Detail Tab

When a session submits a set of SQL or a transaction, there are many different combinations of methods the Oracle kernel will use to satisfy the query or transaction. The Access Pattern Detail tab displays all currently connected sessions, their demographic information, and a count of the various different methods that Oracle uses to handle incoming requests. The table below lists the information available on this tab:
## I/O View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>

Space View (Oracle Performance Analyst)

In addition to a Home page, the Space category of Oracle Performance Analyst includes the following tabbed pages:

- Extent Analysis Tab
- Object Space Tab
- Fragmentation Tab
- Tablespace Detail Tab
- Tablespace Growth Tab
- User Space Tab

Home

The Space Home page includes the following sections:

- Bottleneck Analysis Pane
- Redo Logs
- Space Analysis Pane
- SQL Analysis Pane
- User Space Analysis Pane

Space Analysis Pane

The Oracle tablespace is the logical container for the physical storage needs of a database. The Space Analysis section displays details for all the tablespaces for a particular database, including their total, used, free space, and percent free, as well as if each can automatically extend to support incoming space requests.

Metrics

If any tablespace’s free space percent amount goes below 10%, and at least one tablespace’s datafiles does not have AUTOEXTEND enabled (or the datafile has reached its extend limit), you should take action to ensure that the tablespace does not run out of available free space.

Correction

There are two things you can do to ensure that a tablespace does not run out of available free space:
1. First, you should look into the use of Oracle’s AUTOEXTEND feature. AUTOEXTEND lets you give an Oracle tablespace the ability to auto-grow when it has exhausted the free space contained within. You can let a tablespace grow in an unlimited fashion or put constraints on it to stop at a certain point. You can also dictate how much more free space the tablespace gets each time it needs more space than is available. However, AUTOEXTEND enabled for a tablespace does not mean that you cannot run out of space. Remember you still have the physical server limitations to contend with. Make sure you (or your sysadmin) keep a careful eye on the server drives that house your Oracle database files for available free space.

2. If the free space on a server drive nears its limit, disable AUTOEXTEND for the datafile(s) that are on the target drive, and use the ALTER TABLESPACE ... ADD DATAFILE command to place a new datafile for the tablespace on another drive that has more free space to offer.

Tip: AUTOEXTEND is not a replacement for proactive space planning. When extra space is needed by the database, and AUTOEXTEND is activated by Oracle, performance slows as Oracle allocates more space for the tablespace. Avoiding AUTOEXTEND aids performance, albeit in a small way.

Bottleneck Analysis Pane

When using bottleneck analysis to troubleshoot a database, you cannot rely only on the information contained in the wait event views that Oracle provides. For example, an object may attempt to extend into another extent of space in a tablespace and yet be denied if no such free space exists. Such a failure is not reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that you cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain an accurate performance risk assessment. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system. The Performance Analyst Space home page displays space-related bottlenecks that can decrease overall performance of your system.

The following bottleneck indicators are used on the Performance Analyst Space home page to succinctly communicate the general overall space situation of the monitored database:

- Autoextend Datafiles at Extend Limit
- Objects at Maximum Extents
- Objects with No Room to Expand
- Offline Tablespaces
- Top Fragmented Datafiles
Autoextend Datafiles at Extend Limit

You can specify that one or more tablespace datafiles can automatically grow by enabling the datafile’s AUTOEXTEND property. You can also specify that the datafile not be permitted to grow beyond a certain limit, and once that limit is reached, the datafile and/or the tablespace may be permanently out of space.

Location  Oracle Performance Analyst Statistics > Space View (DBArtisan - Oracle Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  You should not see any positive indicator that any datafile has reached its extend limit. While it might be okay from the standpoint that a datafile cannot simply grow anymore (if the tablespace has other datafiles that can grow or that no more space is added to the tablespace), disable AUTOEXTEND on the datafile.

Correction  If a datafile has reached its extend limit, you can take a number of actions: Eliminate the extend limit for the datafile either by increasing the limit size or allowing to grow in an unlimited fashion. If the datafile is on a disk or file system that has no free space left, you can add another datafile to the tablespace to allow for space expansion and alter the problem datafile to have AUTOEXTEND disabled. If the datafile is on a disk or file system that has no free space left, the datafile can be physically relocated to another drive or file system with more free space.

Objects at Maximum Extents

When an object in Oracle (table, index, table partition, etc.) needs to expand, Oracle automatically allocates another extent of space to accommodate the incoming data. However, a table or index can reach its maximum extent limit, which is the maximum number of extents for an object.

Location  Oracle Performance Analyst Statistics > Space View (DBArtisan - Oracle Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Unless an object is static in nature, and is not expected to grow in size, no object should ever get to its maximum extent limit.

Correction  If a maximum extent limit is reached for an object, you can take a number of actions: The object can be reorganized into a locally-managed tablespace where no maximum extent limit is applied to any object. The object can be altered to have unlimited extents. The object can be reorganized into one or a few extents.

The good news concerning locally-managed tablespaces is that unlimited extents are the rule, so if you choose to use these storage structures in your database, you will not have to worry about an object ever reaching a maximum extent limit. Some DBAs have expressed concerns over whether an object having hundreds or thousands of extents experiences performance problems when full table scans or similar operations are performed against them. While most Oracle experts agree that such I/O degradation might have been experienced in earlier Oracle versions, most feel that such is not the case any longer, especially when locally-managed tablespaces are used.
Objects with No Room to Expand

When an object in Oracle (table, index, table partition, etc.) needs to expand, Oracle automatically allocates another extent of space to accommodate the incoming data. However, an object may be prohibited from expanding for a number of reasons:

- The tablespace does not have enough free space to accommodate the extent request, and cannot automatically extend.
- The tablespace has enough total free space, but the space is not contiguous in nature (and the tablespace cannot automatically extend) and therefore the object cannot extend.

Correction

If an object cannot extend, you can take a number of actions including:

- One or more of the tablespace’s datafiles can have its AUTOEXTEND property enabled, which lets the object to grow even though there is no space currently available in the tablespace.
- The object can be reorganized into a locally-managed tablespace all extents are uniform in nature.
- The object can be altered to have a reduced next extent size.

Offline Tablespaces

A tablespace ONLINE status indicates that the tablespace is in normal read/write mode. Tablespaces marked read only displays a status of READ ONLY, while tablespaces engaged in backup mode indicates such in their status. An OFFLINE tablespace during normal processing hours is a cause for concern.

Correction

If a tablespace has a status of OFFLINE, you can make it ONLINE using the ALTER TABLESPACE command.

Top Fragmented Datafiles

This section shows the tablespaces datafiles suffering from the highest levels of free space fragmentation in the database. Tablespaces are made up of object segments and space extents. Extents are either allocated to object segments or are free. When a tablespace is initially populated, all objects are neatly packed together in the front of the tablespace and all remaining free space is in one free chunk at the end. As objects grow
(or extend) they are given new extents of space in the tablespace/datafile. If they are dropped, pockets of free space begin to appear throughout the tablespace. These pockets of space take one of two forms. The table below describes these forms:

<table>
<thead>
<tr>
<th>Free Space</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Honeycombs</td>
<td>Pockets of free space that are adjacent to one another.</td>
</tr>
<tr>
<td>Bubbles</td>
<td>Pockets of free space that are trapped between object extents in the tablespace.</td>
</tr>
</tbody>
</table>

**Correction**

You can eliminate honeycomb fragmentation with the ALTER TABLESPACE...COALESCE command. Issuing this command combines all pockets of adjacent free space into one extent. Each database maintenance plan should include a job that coalesces all the free honeycombs in a tablespace into one free chunk. Although Oracle is supposed to perform this operation automatically through the SMON process, it requires you to have the PCTINCREASE parameter of the tablespace set to a nonzero value. Having PCTINCREASE set to a value greater than zero encourages tablespace fragmentation through disparately sized extents. Plus, using SMON in this way is not efficient or entirely reliable.

You can temporarily solve bubble fragmentation by performing a total tablespace reorganization. A better long-term solution for Oracle databases 8.1.5 or later is to convert tablespaces over to locally managed tablespaces. With locally managed tablespaces you either specify the initial extent size and let Oracle automatically size all other extents, or specify a uniform extent size for everything. Problems caused by fragmentation then become a thing of the past.

To help stave off fragmentation problems:

- Set PCTINCREASE to zero for all tablespaces and objects to promote same-sized extents.
- Specify equal-sized allotments for your INITIAL and NEXT object storage parameters.
- Group objects with like growth and storage needs together in their own tablespaces.
- Considering converting any dictionary-managed tablespace to locally-managed.

You should also avoid fragmentation in the SYSTEM tablespaces. The best ways to do this include:
Ensure no user has a DEFAULT or TEMPORARY tablespace assignment of SYSTEM.

Ensure no user has a quota set for SYSTEM.

Ensure no user has been granted the UNLIMITED TABLESPACE privilege.

**SQL Analysis Pane**

Much of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end user response times.

The SQL Analysis section of the Space home page shows a count of all SQL statements that have executed INSERT, UPDATE, DELETE, and TRUNCATE commands. Seeing these statistics should help you determine how much space-related SQL activity is occurring on your system.

**Metrics**

The statistics for this section can be used in many different ways. For example, large numbers of inserts could indicate a growing database and that you should keep a watchful eye on free space. Heavy update numbers could mean trouble for objects containing many indexes (indexes typically undergo splits and fragmentation when large volumes of updates are thrown their way). Many deletes might signal potential table high water mark problems.

**Redo Logs**

Oracle’s redo logs are hotbeds of I/O activity in databases that store heavily modified data. Redo log files are used to perform database recovery in the event of a system crash. Redo logs are written to in a cyclical fashion - each log file is filled up before Oracle moves on to the next file. The redo bytes statistic reflects the total amount of redo generated in bytes since the last refresh. The redo wastage bytes indicate how many bytes were wasted by redo log buffers being written before they were full.

**Location**

Oracle Performance Analyst Statistics > Space View (DBArtisan - Oracle Performance Analyst) > Home > SQL Analysis Pane

**Metrics**

Viewing a high percentage of wasted bytes to overall redo bytes can help you identify if redo wastage is a problem on your system.

**Correction**

Sometimes heavy redo wastage occurs when the log_checkpoint_interval parameter is set too high. To fix this: Edit the Init.ora file for the database. Change the amount of log_checkpoint_interval to a lower value. Cycle the Oracle server when possible to allow the new value to take effect. Monitor new value to see if performance improves. For Oracle9i and later, you can dynamically alter the log_checkpoint_interval parameter without stopping/starting the database.

**User Space Analysis Pane**

The Top Space Hogs section details the schema in the database that own the most space. In databases where object owners can be many, it is oftentimes a good idea to
take a quick look at which schema are leading the way in terms of space usage. This is not restricted to production environments only, but can be extended to dynamic development systems as well, especially if there are many developers in a database that have their own sets of objects. Developers sometimes have a bad habit of creating objects (or copies of objects) that they leave in a database even though they are not being used.

Correction: If a user owns many objects, or copies of objects, you can reclaim space in your database by contacting the user to see if those objects can be dropped.

### Tablespace Detail Tab

The Tablespace Detail tab includes the following sections:

- [Datafile Detail](#)
- [Tablespace Object Summary](#)

### Tablespace Object Summary

Tablespaces are the logical containers for database objects inside Oracle. The Tablespace Object Summary section provides an overview of how much space is consumed in each tablespace by object type. The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace Name</td>
<td>The name of the tablespace.</td>
</tr>
<tr>
<td>Status</td>
<td>Indicates the status of the tablespace.</td>
</tr>
<tr>
<td>Autoextend</td>
<td>Indicates whether one or more of the tablespace's datafiles has the ability to automatically grow.</td>
</tr>
<tr>
<td>Total Space (MB)</td>
<td>The total allocated space for the tablespace.</td>
</tr>
<tr>
<td>Table (MB)</td>
<td>The amount of used table and table partition space, in MB.</td>
</tr>
<tr>
<td>Index (MB)</td>
<td>The amount of used index and index partition space, in MB.</td>
</tr>
<tr>
<td>Rollback (MB)</td>
<td>The amount of used rollback and undo segment space, in MB.</td>
</tr>
<tr>
<td>Cluster (MB)</td>
<td>The amount of used cluster space, in MB.</td>
</tr>
<tr>
<td>LOB (MB)</td>
<td>The amount of used large object space, in MB.</td>
</tr>
</tbody>
</table>
Datafile Detail

Tablespaces are the logical containers for database objects inside Oracle, and datafiles are the actual physical files that make up a tablespace. The Datafile Detail section provides an overview of the size of each datafile and other demographic information. The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>The name of the datafile.</td>
</tr>
<tr>
<td>Status</td>
<td>Indicates the status of the tablespace.</td>
</tr>
<tr>
<td>Autoextend</td>
<td>Indicates whether the datafile has the ability to automatically grow.</td>
</tr>
<tr>
<td>Tablespace Name</td>
<td>The name of the tablespace.</td>
</tr>
<tr>
<td>Size (MB)</td>
<td>The total allocated space for the datafile.</td>
</tr>
<tr>
<td>Max Size (MB)</td>
<td>The maximum size the datafile can automatically grow to.</td>
</tr>
</tbody>
</table>

Object Space Tab

The Object Space tab displays a summary of space and extent information for all or selected objects in the database. The table below lists the information available on this tab:
Space View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>The owner of the object.</td>
</tr>
<tr>
<td>Object Name</td>
<td>The name of the object.</td>
</tr>
<tr>
<td>Object Type</td>
<td>The type of object (table, index, etc.).</td>
</tr>
<tr>
<td>Space (KB)</td>
<td>The size of the object in KB.</td>
</tr>
<tr>
<td>Extents</td>
<td>The number of extents used by the object.</td>
</tr>
<tr>
<td>Max Extents</td>
<td>The maximum number of extents allowed for the object.</td>
</tr>
<tr>
<td>Initial Extent (KB)</td>
<td>The initial extent size for the object.</td>
</tr>
<tr>
<td>Next Extent (KB)</td>
<td>The next extent size for the object.</td>
</tr>
<tr>
<td>Tablespace</td>
<td>The tablespace where the object resides.</td>
</tr>
</tbody>
</table>

**Metrics**

One thing to keep an eye on are objects that are close to their maximum extent limit. Such objects can be altered to have more or unlimited extents if need be. The use of locally-managed tablespace eliminates the threat of an object ever encountering a maximum extent limit. For more information, see the Home page under Space View (DBArtisan - Oracle Performance Analyst).

**Tablespace Growth Tab**

Growing tablespaces do not have to spell problems for a DBA. Of course, up front planning is the key to sizing tablespaces correctly. Unfortunately, DBAs may not have all the information they need at tablespace creation time (or they may have the wrong information), so a tablespace can approach the end of its free space from time to time. The DBA can allow a tablespace to grow automatically (AUTOEXTEND) to prevent an out-of-space condition. Enabling AUTOEXTEND for a tablespace is quite reassuring for a DBA, but it introduces a new concept for the tablespace: monitoring data file growth. You should monitor your tablespaces that have AUTOEXTEND set so you can get an idea of the growth that is occurring in your database. Monitoring them lets you perform some mini-capacity planning and helps you get a jump-start on server upgrades.

The Tablespace Growth tab displays growth statistics for the database currently being monitored. The table below lists the information available on this tab:
### Space View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace Name</td>
<td>The name of the tablespace.</td>
</tr>
<tr>
<td>Datafile Name</td>
<td>The name of the tablespace’s datafile.</td>
</tr>
<tr>
<td>Autoextend</td>
<td>Indicates whether the tablespace has one or more datafiles that have the</td>
</tr>
<tr>
<td></td>
<td>AUTOEXTEND feature set (allowing the datafile to automatically grow).</td>
</tr>
<tr>
<td>Created Size</td>
<td>The starting size for the physical datafile.</td>
</tr>
<tr>
<td>Current Size</td>
<td>The current size of the physical datafile.</td>
</tr>
<tr>
<td>Growth</td>
<td>The percentage of growth experienced for the datafile (if any).</td>
</tr>
</tbody>
</table>

#### Metrics

Using AUTOEXTEND can be very important for tablespaces devoted to disk sorting. Large data warehouses often must endure large disk sort operations. Having AUTOEXTEND enabled for tablespaces used for temporary segments (sort activity) helps large sort queries to complete when they might otherwise fail due to running out of sort space.

Just having AUTOEXTEND enabled for a tablespace does not mean you cannot run out of space. Remember, you still have to contend with the physical server limitations. Make sure you (or your sysadmin) keep a careful eye on the server drives that house your Oracle database files for available free space. If the free space on a server drive nears its limit, disable AUTOEXTEND for the datafile(s) that are on that drive, and use the traditional ALTER TABLESPACE...ADD DATAFILE command to place a new datafile for the tablespace on another drive that has more free space to offer.

### Fragmentation Tab

Tablespaces are made up of object segments and space extents. Extents are either allocated to object segments or are free. When a tablespace is initially populated, all objects are neatly packed together in the front of the tablespace and all remaining free space are in one free chunk at the end. Unfortunately, this is not how things continue to be in a tablespace. As objects grow (or extend) they are given new extents of space in the tablespace. If you drop objects, pockets of free space begins to appear throughout the tablespace. These pockets of space are either honeycombs or bubbles. Honeycombs are not so difficult to deal with, but bubbles are another story.

The Fragmentation tab displays two different views of tablespace fragmentation. The first grid displays fragmentation at the tablespace level and the second grid displays fragmentation at the datafile level. The table below describes the information available in the Tablespace Fragmentation grid:
Space View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace Name</td>
<td>The tablespace name.</td>
</tr>
<tr>
<td>Free Space (MB)</td>
<td>The total amount of free space in MB for the tablespace.</td>
</tr>
<tr>
<td>Free Chunks</td>
<td>The total number of free chunks in the tablespace.</td>
</tr>
<tr>
<td>Largest Chunk (MB)</td>
<td>The largest free chunk (in MB) for the tablespace.</td>
</tr>
</tbody>
</table>

The table below describes the information available in the Datafile Fragmentation grid on the Fragmentation tab:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datafile</td>
<td>The name of the datafile.</td>
</tr>
<tr>
<td>Autoextend</td>
<td>Indicates whether the datafile can automatically grow in size.</td>
</tr>
<tr>
<td>Tablespace</td>
<td>The tablespace name.</td>
</tr>
<tr>
<td>Free Chunks</td>
<td>The number of free chunks in the datafile.</td>
</tr>
<tr>
<td>Largest Chunk</td>
<td>The largest free chunk (in MB) for the datafile.</td>
</tr>
</tbody>
</table>

**Metrics**

To spot and correct fragmentation in your tablespaces, you should periodically monitor the fragmentation levels of your tablespaces at a global level. Doing so helps you quickly spot tablespaces that are experiencing fragmentation issues. Seeing a tablesnapce with only one chunk of free space is a sign that a tablesnapce is not having fragmentation problems. Seeing a tablesnapce with a couple of free chunks may not be a big deal either, because the tablesnapce could be made up of more than one datafile. Each datafile has its own chunk or chunks of free space.

If you see a tablesnapce that has many chunks of free space, the next thing to do is drill down into it and find out if the tablesnapce is experiencing honeycomb or bubble fragmentation. Honeycomb fragmentation occurs when pockets of free space exist that are adjacent to one another. Bubbles are pockets of free space that are trapped between object segment extents.

You can eliminate honeycomb fragmentation with the ALTER TABLESPACE...COALESCE command. This command combines all pockets of adjacent free space into one extent. It is important to do this because when an object is newly introduced to a tablesnapce (or an existing object needs to extend), and a contiguos chunk of free space does not exist to accommodate an object's INITIAL or NEXT size allocation, Oracle must manually coalesce all available honeycombs to try and form a large enough free chunk. This is a performance hit. If possible, you should try to minimize performance hits.

Bubble fragmentation is a more serious matter and is normally only corrected through tablespace or database reorganization. The standard technique is to perform an export
of all objects in the tablespace, drop the tablespace, and then import all the objects back into the tablespace. However, this technique may just treat the symptom and not the cause of bubble fragmentation. The real issue is to address the reuse of space extents within a tablespace so that bubble fragmentation does not occur in the first place.

Oracle8 and later offers the concept of locally-managed tablespaces, which can all but eliminate tablespace fragmentation. It totally does away with the storage parameters of MINEXTENTS, MAXEXENTS, PCTINCREASE, and NEXT. With locally managed tablespaces you either specify the initial extent size and let Oracle automatically size all other extents, or specify a uniform extent size for everything. Problems caused by fragmentation then become a thing of the past.

**Correction**

What can you do manually to help stave off fragmentation problems? A few suggestions include:

- Set PCTINCREASE to zero for all tablespaces and objects to promote same-sized extents.
- Specify equal-sized allotments for your INITIAL and NEXT object storage parameters.
- Group objects with like growth and storage needs together in their own tablespaces.

Of all your tablespaces, you want to avoid fragmentation problems in your SYSTEM tablespace the most as this is the major hotbed tablespace for Oracle activities. The easiest way to avoid this is to not allow any user (even the default DBA ID's SYS and SYSTEM) to have access to it. There are three ways to do this:

1. Ensure no user has a DEFAULT or TEMPORARY tablespace assignment of SYSTEM.
2. Ensure no user has a quota set for SYSTEM.
3. Ensure no user has been granted the UNLIMITED TABLESPACE privilege.

**Extent Analysis Tab**

Object fragmentation results when objects consume multiple extents of space in a tablespace rather than a single block of space. Although performance problems with respect to object fragmentation are not as severe as they were in previous versions of Oracle, some DBAs believe that response-time penalties can still be chalked up to this situation. When multiple extents exist for an object, the amount of time it takes Oracle to scan it can be longer than if the object was made up of only one extent. This typically holds true when extents are scattered on different parts of the physical server disk. In addition, a performance hit is taken each time an object must extend into another extent of space.
The Extent Analysis tab displays objects whose extent count has exceeded a user-suggested numerical limit. The table below lists the information available on this tab if any objects are found:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>The user account that owns the object.</td>
</tr>
<tr>
<td>Object Name</td>
<td>The name of the object.</td>
</tr>
<tr>
<td>Object Type</td>
<td>The type of object (TABLE, INDEX, etc.).</td>
</tr>
<tr>
<td>Next Extent</td>
<td>The next extent amount of space the object will consume.</td>
</tr>
<tr>
<td>Total Extents</td>
<td>The number of extents the object is currently consuming.</td>
</tr>
<tr>
<td>Max Extents</td>
<td>The MAXEXTENTS limit imposed on the object by the DBA.</td>
</tr>
<tr>
<td>Largest Free Chunk (KB)</td>
<td>The size of the largest chunk.</td>
</tr>
<tr>
<td>Tablespace Name</td>
<td>The name of the tablespace.</td>
</tr>
</tbody>
</table>

**Metrics**

When is object fragmentation a problem for an object? Opinions on this vary widely. As a general rule of thumb, if an object is exhibiting response time degradations, and no other factor can be attributed to the slowdown, examine the object to see how badly fragmented it is. If extent numbers are seen exceeding 100 or more, than you might want to think about reorganizing the object or using locally managed tablespaces. This rule of thumb does not apply to objects assigned to locally-managed tablespaces as extent fragmentation is expected and not a performance issue.

**Correction**

The best preventative for this problem is specifying the correct allocation of space for the object in the first place, but what can you do if you have objects with high numbers of extents? For tables and indexes you have three options:

1. Use Oracle’s export/import utility to export, drop, and import the fragmented objects back into the database with the export parameter COMPRESS=Y. This will bring the objects back into the database with one large extent. Make sure that large enough chunks of available free space exist to accept the object back in, or you may experience space allocation errors.

2. With Oracle8, you can use the ALTER TABLE ... MOVE command to reorganize a table back into one extent in a very safe and efficient manner.

3. Use ALTER INDEX ... REBUILD to reorganize indexes that have moved into multiple extents.

Another thing to keep an eye on is the next extent size of an object vs. the largest free chunk of space in the tablespace. Seeing objects with larger next extents than free space may signal a problem unless the tablespace can automatically extend to accommodate the object’s next extent.
User Space Tab

The User Space tab includes the following sections:

- Top Space User Accounts
- User Space Detail

Top Space User Accounts

It is vital that a DBA know how the various accounts assigned to a database consume space. This is true in either production or development databases, because even in development databases, space can become an issue that causes major headaches. If development accounts are creating and cloning many objects without removing them, the result can be a lot of wasted space.

The Top Space User Accounts statistic shows how much total allocated space the top twenty accounts possess in the database.

Location Oracle Performance Analyst Statistics > Space View (DBArtisan - Oracle Performance Analyst) > User Space Tab

Metrics Seeing owner account with larger than expected data volumes could warrant further investigation. In addition, seeing accounts that have objects in more tablespaces than they have quota's for should also cause you to examine their account more closely to ensure the correct space privileges are in place.

User Space Detail

The User Space Detail section allows you to drill-down and see the specifics of the Top Space User accounts.

Location Oracle Performance Analyst Statistics > Space View (DBArtisan - Oracle Performance Analyst) > User Space Tab
Objects View (Oracle Performance Analyst)

In addition to a Home page, the Objects category of Oracle Performance Analyst includes the following tabbed pages:

- Hot Objects Tab
- Invalid Objects Tab
- Objects Summary Tab
- Tables/Indexes in Same Tablespace Tab

Home

The Objects Home page includes the following sections:

- Bottleneck Analysis Pane
- Key Ratio Analysis Pane
- SQL Analysis Pane
- Object/Buffer Pool Placement Pane
- User Object Analysis Pane

Key Ratio Analysis Pane

Object-related database activity can be examined using both ratio-based and wait/bottleneck-based analysis. Ratio-based analysis involves examining a number of key database ratios and statistical readings that can be used to indicate how active certain object types are. Performance ratios serve as roll-up mechanisms for busy DBAs to use for at-a-glance performance analysis.

When using ratio-based analysis, there are some standards to adhere to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that you examine come from the v$systat performance view. The performance view maintains a count of all the occurrences (in the VALUE column) of a particular database incident (in the NAME column) since the database was brought up. For databases that are kept up for long periods of time, these values can grow quite large and impacts how a particular ratio is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each database’s individual ‘personality’
with respect to the key performance ratios. Some hard and fast rules simply do not apply
to every database. The danger in using blanket ratio standards is that they can lead you
to haphazardly take action, which can at times contribute nothing to the situation, and
sometimes even degrade performance.

The following ratios are used on the Performance Analyst Objects home page to
succinctly communicate the general session-based performance levels of the monitored
database:

- Active Rollback Ratio
- Chained Row Fetch Ratio

The following statistic, available on this pane, duplicates a statistic available on the Key
Ratio Analysis Pane of the Home View (Oracle Performance Analyst) page:

- Rollback Contention Ratio

**Active Rollback Ratio**

To undo changes made to the Oracle database from within a transaction, Oracle writes
data to individual rollback segments. You can also use these to maintain read
consistency for multiple users of modified data. Because Rollback Segments read and
write data, they can become very hot areas for I/O. This statistic is a ratio that displays
the percentage of rollback segments currently involved in work.

Seeing consistent ratios of 80% or higher could indicate the need for more rollback
segments on the database.

**Chained Row Fetch Ratio**

In normal circumstances, a row of data should fit completely inside one Oracle block.
Sometimes, however, this is not the case and the table suddenly contains chained or
migrated rows (rows that span more than one data block).

Chaining occurs when a row is initially too large to fit inside one block. Two or more
blocks are used by Oracle to hold the row. Migration deals with rows that have grown so
much that they can no longer be contained within their original block. When this occurs,
Oracle relocates the row out of its original block into another block, but leaves a pointer
behind to indicate the relocation.

Both chaining and migration force Oracle to perform more than one I/O to retrieve data
that could normally be obtained with a single I/O operation, with the end result being
degraded performance.
The chain row fetch ratio statistic represents the percentage of rows fetched that were of either the chained or migrated row type.

Location
Oracle Performance Analyst Statistics > Objects View (DBArtisan - Oracle Performance Analyst) > Home > Key Ratio Analysis Pane

Metrics
If the amount of chained rows in your tables exceeds 25-30%, you should take steps to eliminate the problem. Further, if the amount of chained rows accessed in your system vs. total rows accessed approaches 20-30%, you can start the process of eliminating the chained and migrated rows.

Correction
You can locate tables that contain chained rows. Once found, there are a couple of ways to reorganize tables to remove the chaining/migration problem. However, the best way to deal with chained and migrated rows is to prevent them from occurring. The table below describes two methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use a large block size</td>
<td>Because chaining and migrations occur when the Oracle block is too small to hold the rows in question, make sure you are using a large enough block size for each database you create. An 8KB block size or higher is normally recommended to help stave off chained and migrated rows. If you are using Oracle9i or later, you can create special tablespaces that have larger block sizes (16-32KB) than the overall database block size and place any table that is a candidate for chained/migrated rows into them.</td>
</tr>
<tr>
<td>Use proper values of PCTFREE for tables</td>
<td>The necessary amount of percent free in a table helps prevent row migrations from occurring. If you have a database that houses rows with the potential to grow substantially over their initially inserted size, provide a liberal amount of PCTFREE for each of your tables.</td>
</tr>
</tbody>
</table>

Bottleneck Analysis Pane

When using bottleneck analysis to troubleshoot a database, you cannot rely only on the information contained in the wait event views that Oracle provides. For example, an object attempts to extend into another extent of space in a tablespace and yet be denied if no such free space exists. Such a failure is not reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that you cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain an accurate performance risk assessment. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system. The Performance Analyst Objects home page displays object-related bottlenecks decreases the overall performance of your system.

The following bottleneck indicators are used on the Performance Analyst Objects home page to communicate the general overall conditions of objects in the monitored database:
Chained Tables

A row of data should fit completely inside one Oracle block. Sometimes, a table suddenly contains chained or migrated rows, which are rows that span more than one data block.

Chaining occurs when a row is initially too large to fit inside one block. Two or more blocks are used by Oracle to hold the row. Migration deals with rows that have grown so much that they can no longer be contained within their original block. Oracle relocates the row out of its original block into another block, but leaves a pointer behind to indicate the relocation.

Both chaining and migration force Oracle to perform more than one I/O to retrieve data that could normally be obtained with a single I/O operation, with the end result being degraded performance.

The Chained Tables statistic identifies the number of tables in the database that contain chained or migrated rows.

Location  Oracle Performance Analyst Statistics > Objects View (DBArtisan - Oracle Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics Seeing many chained/migrated tables could indicate a database whose block size is undersized. However, even one chained/migrated row table can be a problem if that table is an often-referenced or scanned table.

Correction

You can locate the actual tables that contain chained/migrated rows. Once found, there are a couple of ways to reorganize tables to remove the chaining/migration problem.
However, the best way to deal with chained and migrated rows is to prevent them from occurring. The table below describes two methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use a large block size</td>
<td>Because chaining and migrations occur when the Oracle block is too small to hold the rows in question, make sure you are using a large enough block size for each database you create. An 8KB block size or higher is normally recommended to help stave off chained and migrated rows. If you are using Oracle9i or later, you can create special tablespaces that have larger block sizes (16-32KB) than the overall database block size and place any table that is a candidate for chained/migrated rows into them.</td>
</tr>
<tr>
<td>Use proper values of PCTFREE for tables</td>
<td>The necessary amount of percent free in a table helps prevent row migrations from occurring. If you have a database that houses rows with the potential to grow substantially over their initially inserted size, provide a liberal amount of PCTFREE for each of your tables.</td>
</tr>
</tbody>
</table>

For more information, see [Bottleneck Analysis Pane](#).

**Session Blocks**

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Although Oracle supports unlimited row-level locking, blocking lock situations do crop up. Blocks are most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency.

**Note:** This statistic is also called [Current Object Blocks](#) on the [Home View (Oracle Performance Analyst)](#) page, and [Sessions Blocked](#) on the [Users View (Oracle Performance Analyst)Home](#) page.
Invalid/ Objects

Objects like procedures, packages, functions, triggers, and views can become invalidated for a variety of reasons. The main cause is generally a dependent object that has been altered or removed from the system. However, other objects, like indexes, can become invalid also due to scenarios like SQL*Loader problems. If an object that has become invalid is still referenced (through an application or SQL query tool), a variety of problems can result. Sometimes Oracle reports a clear error stating the problem, while other times seemingly odd behavior is exhibited by the database.
Metrics

There is no reason to have invalid objects in a production database. If your production databases have invalid objects that are no longer needed, promptly remove them from each system. Any needed objects that are indicating an invalid status should quickly be fixed before access problems develop. It is very normal for development databases to have invalid objects because developers create, modify, and compile objects all the time. The only invalid object that really should not be present in either a development or production database is an invalid index.

Correction

If code objects have become invalidated, you can issue an ALTER ... COMPILE command to see if they compile properly and become valid once again. If they do not, then check the USER_ERRORS view for any resulting error messages. Indexes can be validated once more by using the ALTER INDEX ... REBUILD command.

Locked Objects

Locked Objects is a count of all objects on the system that currently have some form of lock against them.

Note: Drilling down into the count of locked objects displays detail on each object that is locked, along with the user process holding the lock and the type of lock held.

Table High Water Mark Problems

One form of object fragmentation revolves around what is called a table’s high water mark. Tables that are the victim of much insert-delete activity can develop performance problems due to wasted space being present. A table’s high-water mark equals the last block in the table that was used to hold data. The problem in Oracle is that this high-water mark is not reset by DELETE activity, so it is possible for a table to have absolutely no data in it but contain a high-water mark that is many blocks high. When such a table is scanned, Oracle will read up to the high-water mark even if no rows exist in the table at all. This can make for some unnecessarily large scan times. For a real world example, see Bottleneck Analysis Pane.
Metrics Seeing non-zero numbers for this metric could indicate that table scans are taking longer than they should.

Correction Performance Analyst does not currently provide diagnostics that identify the actual tables that contain artificially inflated high water marks. Embarcadero Space Analyst provides all the levels of detail regarding table high water marks plus a reorganization wizard that can reset the high water mark and thereby improve performance of table scans against tables suffering from this problem.

**Tables/Indexes in Same Tablespace**

One common Oracle practice is to physically separate tables and their child indexes onto distinct physical drives or file systems. Doing so reduces the potential for I/O contention when each object is accessed. The Tables/Indexes in Same Tablespace statistic displays a count of all tables whose index(es) reside in the same tablespace as they do.

Correction If the server is configured to allow for intelligent object striping, and you see a large count of tables and indexes that are housed in the same tablespace, you can: Create a separate tablespace for indexes on a drive different than that used for tables, and perform an ALTER INDEX … REBUILD operation on all indexes to move them to the new tablespace. Certain versions of Oracle even allow the rebuild operation to occur online (using the ONLINE keyword of the REBUILD command). Use the export/import utility to move indexes to a new tablespace. Use the ALTER TABLE … MOVE command to move tables to a new tablespace. Index-organized tables can be moved online.

**SQL Analysis Pane**

Certain objects in an Oracle database are accessed more than others. These objects can become a source of contention given certain conditions. The SQL Analysis section of the Objects home page identifies the most accessed tables on the database.
Metrics DML activity against tables can cause contention for space management objects like free lists. Oracle9i or later provides automatic segment management, which can remove problems with free lists and the like.

Object/Buffer Pool Placement Pane

Because data objects can be referenced with different types of usage patterns, Oracle8 offers the option to intelligently place objects into one of three buffer caches. The table below describes the buffer caches:

<table>
<thead>
<tr>
<th>Buffer Cache</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEEP</td>
<td>Designed to minimize misses in the buffer cache. Small objects that are frequently referenced are candidates for the KEEP buffer pool.</td>
</tr>
<tr>
<td>RECYCLE</td>
<td>Designed to avoid having large numbers of infrequently accessed blocks of data crowd out objects that need to be referenced in RAM, the RECYCLE pool is good for large objects that are scanned from beginning to end without the need for keeping all their data in RAM.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>The traditional cache for all other data objects.</td>
</tr>
</tbody>
</table>

**Note:** Unless you specify the KEEP or RECYCLE buffer cache, Oracle automatically places objects into the DEFAULT buffer cache.

The Object/Buffer Pool Placement section identifies how many objects are currently assigned to the various caches.
Objects View (Oracle Performance Analyst)

Location:  [Oracle Performance Analyst Statistics] > [Objects View (DBArtisan - Oracle Performance Analyst)] > [Home] > [SQL Analysis Pane]

Metrics: When looking at overall database I/O activity, you should keep an eye out for objects that you can place into a particular buffer cache. Consider using a KEEP cache for relatively small, frequently accessed tables that require fast response times. Large tables with random I/O activity and are scanned from beginning to end are good candidates for a RECYCLE cache.

Correction: Objects can be placed into different buffer pools at object creation time (using the STORAGE... BUFFER_POOL option in Oracle8 or later) or existing objects can be set into a different pool with the ALTER command. NOTE: Tables, partitions, and indexes can be placed into the different caches. If you just want to use the DEFAULT buffer pool and not enable any special caches, you can still encourage Oracle to keep certain objects in the cache as long as possible using the CACHE parameter. For example, issuing the command ALTER TABLE...CACHE specifies that the blocks retrieved for a table be placed at the most recently used end of the LRU list in the DEFAULT buffer cache when a full table scan is performed. You can also use the CACHE hint in SQL statements to cache a table, but used in this form, the blocks are only cached until the next time the database is shut down.

User Object Analysis Pane

All objects are created inside of user accounts called schema. The User Object Analysis section of the Performance Analyst Objects home page shows schema that are ranked the worst in the several categories. The table below lists the categories:

<table>
<thead>
<tr>
<th>Worst Schema for</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chained Row Tables</td>
<td>The schema containing the most tables with chained rows is identified.</td>
</tr>
<tr>
<td>Invalid Objects</td>
<td>The schema containing the most invalid objects is identified.</td>
</tr>
<tr>
<td>Extent Problems</td>
<td>The schema containing the most objects with maximum extent limit or extent space deficit problems is identified.</td>
</tr>
</tbody>
</table>

Correction: To determine the degree and severity of each type of problem, go into detailed views that present specific information for each type of object problem.

Hot Objects Tab

The Hot Objects tab includes the following sections:

- [Hot Code]
- [Hot Tables]
Hot Tables

Certain objects in an Oracle database are accessed more than others. These objects can become a source of contention given certain conditions. The Hot Tables section identifies tables that are being frequently accessed through various SQL statements. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Owner</td>
<td>The owner of the table.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>Issued Command</td>
<td>The SQL statement command issued against the table.</td>
</tr>
<tr>
<td>Executions</td>
<td>The number of SQL executions the object has experienced.</td>
</tr>
<tr>
<td>Disk Reads</td>
<td>The number of estimated disk reads from the object.</td>
</tr>
<tr>
<td>Buffer Gets</td>
<td>The number of estimated logical I/Os from the object.</td>
</tr>
<tr>
<td>Rows Processed</td>
<td>The number of estimated rows processed from the object.</td>
</tr>
</tbody>
</table>

Location [Oracle Performance Analyst Statistics > Objects View (DBArtisan - Oracle Performance Analyst) > Hot Objects Tab]

Metrics DML activity against tables can cause contention for space management objects like free lists. Oracle9i and later provides automatic segment management, which can remove problems with free lists and the like.

Hot Code

Certain objects in an Oracle database are accessed more than others. Data objects can become a source of contention given certain conditions, while code objects rarely cause contention issues. The Hot Code section identifies code objects (procedure, functions, etc.) that are being frequently accessed through various SQL statements. The table below describes the information available in this section:
Objects View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Owner</td>
<td>The owner of the object.</td>
</tr>
<tr>
<td>Object Name</td>
<td>The name of the objects.</td>
</tr>
<tr>
<td>Object Type</td>
<td>The type of object (package, etc.).</td>
</tr>
<tr>
<td>Executions</td>
<td>The number of estimated executions for the object.</td>
</tr>
<tr>
<td>Loads</td>
<td>The number of times the object was loaded into the shared pool.</td>
</tr>
<tr>
<td>Locks</td>
<td>The number of locks the object has experienced.</td>
</tr>
<tr>
<td>Pins</td>
<td>The number of times the object was pinned in the shared pool.</td>
</tr>
</tbody>
</table>

Location **Oracle Performance Analyst Statistics** > Objects View (DBArtisan - Oracle Performance Analyst) > **Hot Objects Tab**

Metrics Often referenced code objects should be pinned in the shared pool using the Oracle DBMS_SHARED_POOL package. This can also be done through DBArtisan’s pinned code utility. Objects with many executions and loads should be considered candidates for pinning.

**Invalid Objects Tab**

The Invalid Objects tab includes the following sections:

- **Invalid Objects Detail**
- **Invalid Objects Summary**

**Invalid Objects Summary**

Objects like procedures, packages, functions, triggers, and views can become invalidated for a variety of reasons, with the main cause being a dependent object that has been altered or removed from the system. However, other objects, like indexes, can become invalid also due to scenarios like SQL*Loader problems. If an object that has become invalid is still referenced (through an application or SQL query tool), a variety of problems can result. Sometimes Oracle will report a clear error stating the problem, while other times seemingly quirky behavior will be exhibited by the database. In any event, as a DBA you should be on the lookout for objects in your database that have suddenly become invalid.

The Invalid Objects Summary section displays a count of the various objects in the database that are invalid.
Invalid Objects Detail

Objects like procedures, packages, functions, triggers, and views can become invalidated for a variety of reasons, with the main cause being a dependent object that has been altered or removed from the system. However, other objects, like indexes, can become invalid also due to scenarios like SQL*Loader problems. If an object that has become invalid is still referenced (through an application or SQL query tool), a variety of problems can result. Sometimes Oracle will report a clear error stating the problem, while other times seemingly quirky behavior will be exhibited by the database. In any event, as a DBA you should be on the lookout for objects in your database that have suddenly become invalid.

The Invalid Objects Detail section displays information concerning invalid objects. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Account</td>
<td>The user account that owns the objects.</td>
</tr>
<tr>
<td>Object Name</td>
<td>The name of the invalid object.</td>
</tr>
<tr>
<td>Object Type</td>
<td>The type of object (procedure, view, etc.).</td>
</tr>
<tr>
<td>Created On</td>
<td>The timestamp of when the objects was created.</td>
</tr>
<tr>
<td>Last DDL Date</td>
<td>The last structural modification date for the object.</td>
</tr>
</tbody>
</table>
Objects View (Oracle Performance Analyst)

Location  Oracle Performance Analyst Statistics > Objects View (DBArtisan - Oracle Performance Analyst) > Invalid Objects Tab

Metrics  There is no reason to have invalid objects in a production database. If your production databases have invalid objects that are no longer needed, you should promptly remove them from each system. Any needed objects that are indicating an invalid status should quickly be fixed before access problems develop. Correcting invalid objects like procedures and views often involves performing an ALTER...COMPILE operation. If the object status does not return to VALID, then further examination is warranted. It is very normal for development databases to have invalid objects because developers will no doubt be creating, modifying, and compiling objects all the time. The only invalid object that really should not be present in either a development or production database is an invalid index.

Objects Summary Tab

The Objects Summary tab includes the following sections:

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global Summary</td>
<td>This section displays a count of all user objects in the database (minus SYS and SYSTEM objects).</td>
</tr>
<tr>
<td>User Summary</td>
<td>This section displays a count across user accounts of all the major object types in the database. NOTE SYS and SYSTEM accounts are not included.</td>
</tr>
</tbody>
</table>

Tables/Indexes in Same Tablespace Tab

To help avoid physical I/O contention, it is wise to separate a table and its indexes onto separate physical drives. This is normally accomplished by putting tables into one tablespace (whose datafiles exist on one drive) and their indexes into a different tablespace (whose datafiles exist on another drive).

The Tables/Indexes in Same Tablespace tab identifies indexes whose tables reside in the same tablespace as they do. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Owner</td>
<td>The owner of the table.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>Index Name</td>
<td>The name of the index that resides in the same tablespace as the table.</td>
</tr>
<tr>
<td>Tablespace Name</td>
<td>The name of the tablespace.</td>
</tr>
</tbody>
</table>
Metrics If tables and indexes are found in the same tablespace, then either the table or index should be moved to a different tablespace if the server is set up in such a way that different drives and controllers are available that make the relocation worthwhile. Indexes are traditionally easier to move than tables. They can be relocated through many reorganization tools (like Embarcadero Space Analyst) or through the manual use of the ALTER INDEX … REBUILD command.
In many scenarios, an optimally tuned database may not perform well because there are constraints imposed by the system where the database is running. These constraints may include processes competing with the database sever for resources (CPU, I/O, or Memory), a slow CPU, insufficient or slow I/O devices, and insufficient memory. The OS Statistics page of Performance Analyst lets you examine operating system metrics for the following platforms:

- AIX
- HP-UX

**Note:** To view processor info and swap disk info on an HP-UX box, you need to login as ROOT in the OS login.

- Linux
- Solaris
- Unix
- Windows XP and 2000

**Note:** The statistics available on the OS page depend on the operating system platform.

**Tip:** If you magnify a graph to change back to the original size or minimize the size, close the OS Page and then reopen it again. Performance Analyst displays the graph in its original form and size.

In addition to a Home page, the OS category of Oracle Performance Analyst includes the following tabbed pages:

- CPU Tab
- I/O Tab
- Memory Tab
- Network Tab
- Processes Tab

**Home**

The OS Home page includes the following sections:

- Bottleneck Analysis Pane
- Disk Analysis Pane
- Key Resource Usage Pane
- Memory Analysis Pane
Key Resource Usage Pane

The following ratios are used on the Performance Analyst OS home page to communicate the general overall performance levels of the operating system:

- Disk Time
- Load Average
- Processor Time
- Paged Memory Used (Windows)
- Swap Memory Used (AIX, HP-UX, Linux, Solaris, Unix)

Tip: To open the CPU tab, right-click Processor Time. To open the I/O tab, right-click Disk Time. To open the Memory tab, right-click Paged Memory Used.

Disk Time

The Disk Time statistic is the percentage of elapsed time that the selected disk drive/device was busy servicing read or write requests.

Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Home > Key Resource Usage Pane

Metrics You should avoid consistently seeing values for this statistic greater than 90%.

Correction Add more disk drives and partition the files among all of the drives.

Load Average

The Load Average statistic represents the system load averages over the last 1, 5, and 15 minutes.

Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Home > Key Resource Usage Pane

Metrics High load averages usually mean that the system is being used heavily and response time is correspondingly slow.

Processor Time

The Processor Time statistic indicates the percentage of time the processor is working. This counter is a primary indicator of processor activity.
If your computer seems to be running sluggishly, this statistic could be displaying a high percentage. Upgrade to a processor with a larger L2 cache, a faster processor, or install an additional processor.

**Paged Memory Used**

The Paged Memory Used statistic is the ratio of Commit Memory Bytes to the Commit Limit. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk. The commit limit is determined by the size of the paging file. As the paging file increases, so does the commit limit.

*Note:* This statistic is available for the Windows platform.

This value displays the current percentage value only and not an average. If the percentage of paged memory used is above 90%, you may be running out of memory.

Increase the size of page file.

**Swap Memory Used**

The Swap Memory Used statistic is the percentage of swap space currently in use.

If the percentage of swap memory used is above 90%, you may be running out of memory.

Increase the size of your swap files.

**Bottleneck Analysis Pane**

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Average Disk Queue Length
- Interrupts/Sec
- Network Output Queue Length/Network Queue Length
- Processor Queue Length
Tip: To open the I/O tab, right-click any Details menu item. To open the CPU tab, right-click the Item Processor Queues Length Details menu item. To open the Network tab, right-click Network Output Queues Length.

Note: The statistics available in this section depend on the platform of operating system.

**Average Disk Queue Length**

The Average Disk Queue Length statistic is the average number of both read and write requests that were queued for the selected disk during the sample interval.

Location: Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics: This metric is useful in identifying I/O related bottlenecks. If the disk queue lengths for certain disks are consistently much higher than others, you may need to redistribute the load among available disks. If the disk queue lengths for all disks are consistently large, and you see a high amount of I/O activity, your disks may be inefficient.

Correction: Some things you can do if you have problems with this statistic include: Redistribute the data on the disk with the large average disk queue to other disks. Upgrade to faster disk(s).

**Interrupts/Sec**

Interrupts/Sec is the average rate, in incidents per second, at which the processor received and serviced hardware interrupts. This value is an indirect indicator of the activity of devices that generate interrupts, such as the system clock, the mouse, disk drivers, data communication lines, network interface cards, and other peripheral devices. These devices normally interrupt the processor when they have completed a task or require attention. Normal thread execution is suspended. The system clock typically interrupts the processor every 10 milliseconds, creating a background of interrupt activity. This statistic shows the difference between the values observed in the last two samples, divided by the duration of the sample interval.
Network Output Queue Length/Network Queue Length

The Network Output Queue Length statistic is the number of threads in the processor queue.

**Note:** The name of this statistic depends on the platform of the operating system.

Metrics Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than 10 threads per processor is normally acceptable, dependent of the workload.

Correction A sustained high value in the Processor Queue Length could indicate that a processor bottleneck has developed due to threads of a process requiring more process cycles than are available. If this is the case, you should look at installing a faster (or an additional) processor.

Page Faults/Sec

The Page Faults/Sec statistic is the overall rate faulted pages are handled by the processor. It is measured in numbers of pages faulted per second. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults and soft faults.
OS View (Oracle Performance Analyst)

Metrics This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Correction If the number of page faults remains consistently high, you can check with your Windows System Administrator for further investigation. Often, large numbers of page faults are not a problem so long as they are soft faults. However, hard faults, that require disk access, can cause delays.

Processor Queue Length

The Processor Queue Length statistic is the number of threads in the processor queue.

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Home > Bottleneck Analysis PaneOracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > CPU Tab

Metrics Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than 10 threads per processor is normally acceptable, dependent of the workload.

Correction A sustained high value in the Processor Queue Length could indicate that a processor bottleneck has developed due to threads of a process requiring more process cycles than are available. If this is the case, you should look at installing a faster (or an additional) processor.

Processor Speed

The Processor Speed statistic displays the speed of the active processor in MHz. The speed is approximate.

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Home > Bottleneck Analysis Pane

Processor

The Processor Statistic displays the type of processor currently in use, for example, GenuineIntel.
Memory Analysis Pane

The following metrics are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Available Paged Memory (Windows)
- Available Physical Memory
- Available Swap Memory (AIX, HP-UX, Linux, Solaris, Unix)
- Total Paged Memory/Total Swap Memory
- Total Physical Memory

Tip: To open the Memory tab, right-click any Details menu item.

Note: The statistics available in this section depend on the platform of operating system.

Available Paged Memory

The Available Paged Memory statistic shows the amount of virtual memory available for the processes.

Note: This statistic is available for the Windows platform.

Available Physical Memory

The Available Physical Memory statistic represents the amount of RAM available to all processes.
Available Swap Memory

The Available Swap Memory statistic represents the amount of virtual memory available for the processes.

Correction Increase the size of swap files.

Total Paged Memory/Total Swap Memory

The Total Paged Memory statistic shows the maximum amount of virtual memory available to all processes.

Note: The name of this statistic depends on the platform of the operating system.

Total Physical Memory

The Total Physical Memory statistic shows the amount of physical memory installed on your computer.
Metrics This is an informational metric and displays the total amount installed on the machine. Use this value with the available physical memory and paging metrics (Memory details page). If the available physical memory is very small compared to this value, and the paging activity is high, your system may be running low on memory.

**Disk Analysis Pane**

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Free Disk Space
- Total Disk Space
- Used Disk Space

**Tip:** To open the Space tab, right-click any Details menu item.

**Note:** The statistics available in this section depend on the platform of operating system.

**Free Disk Space**

The Free Disk Space statistic shows the unallocated space, in megabytes on all logical disk drives.

**Correction** There are many ways to ensure a database does not encounter a space problem due to physical space limitations: *If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.*

**Used Disk Space**

The Used Disk Space statistic shows the amount of allocated space, in megabytes on all logical disk drives.
Correction There are many ways to ensure a database does not encounter a space problem due to physical space limitations: If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.

Total Disk Space

Total Disk Space displays the total allocated and unallocated space, in megabytes on all logical disk drives.

Correction There are many things a DBA can do to ensure that a database does not encounter a space problem due to physical space limitations, here are two: If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.

Workload Analysis Pane

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- **Number of Logins**
- **Number of Processes**
- **Top CPU Process**
- **Top I/O Process**
- **Top Memory Process**

**Tip:** To open the Processes tab, right-click any Details menu item.

**Note:** The statistics available in this section depend on the platform of operating system.

**Number of Logins**

This statistic displays the total number of logins on the server.
Number of Processes

This statistic displays the total number of processes on the server.

Location: [Oracle Performance Analyst Statistics] > OS View (DBArtisan - Oracle Performance Analyst) > Home > Workload Analysis Pane

Top Memory Process

Top Memory Process shows the current process that is consuming the most amount of memory. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location: [Oracle Performance Analyst Statistics] > OS View (DBArtisan - Oracle Performance Analyst) > Home > Workload Analysis Pane

Metrics: If you are running out of memory on the system, this is a quick way to identify the top memory user. If the displayed process is using a significant portion of the total memory, it could be causing the memory issues.

Top CPU Process

Top CPU Process shows the current process that is consuming the most amount of CPU. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location: [Oracle Performance Analyst Statistics] > OS View (DBArtisan - Oracle Performance Analyst) > Home > Workload Analysis Pane

Metrics: If the amount of CPU time used by this process is close to 100% and the CPU usage is very high, this process may be the bottleneck on the server.

Correction: Investigate the process further to see if it is in an inconsistent state. Also, look at minimum requirements for CPU speed for the process. You may need to upgrade your CPU.

Top I/O Process

The Top I/O Process statistic shows the current process that is consuming the most amount of CPU. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a...
percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Home > Workload Analysis Pane

CPU Tab

The CPU tab of the OS Detail includes the following sections:

- Context Switches/Sec
- CPU Events
- CPU Utilization
- Load Averages

The following statistics available on this tab, are duplicates of statistics available on the Bottleneck Analysis Pane of the OS View (DBArtisan - Oracle Performance Analyst) Home page:

- Interrupts/Sec
- Processor Queue Length

Note: The sections available on this tab depend on the platform of operating system.

CPU Utilization

The CPU Utilization section includes the following information:

- % Privileged Time
- % User Time

% Privileged Time

The % Privileged Time statistic is the percentage of elapsed time that the process threads spent executing code in privileged mode.

Note: For Windows systems, when a Windows system service is called, the service will often run in privileged mode to gain access to system-private data. Such data is protected from access by threads executing in user mode. Calls to the system can be explicit or implicit, such as page faults or interrupts. These kernel commands, are considered privileged to keep the low-level commands executing and prevent a system freeze. Unlike some early operating systems, Windows uses process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. Some work done by Windows on behalf of the application might appear in other subsystem processes in addition to the privileged time in the process.
OS View (Oracle Performance Analyst)

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > CPU Tab

Metrics  The ideal range should be 0-40% (less than 40% indicates excessive system activity).

Correction  If your CPU consistently runs at less than 40% you may need to upgrade your system to include a faster processor(s).

% User Time

The % User Time statistic is the percentage of elapsed time the processor spends in the user mode. User mode is a restricted processing mode designed for applications, environment subsystems, and integral subsystems. The alternative, privileged mode, is designed for operating system components and allows direct access to hardware and all memory. The operating system switches application threads to privileged mode to access operating system services. This counter displays the average busy time as a percentage of the sample time.

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > CPU Tab

Metrics  If the Privileged Time is high in conjunction with Physical Disk Reads, consider upgrading the disk I/O subsystem.

CPU Events

The CPU Events section includes the following information:

- Context Switches/Sec
- Load Averages
- System Calls/Sec

Note: The statistics available in this section depend on the platform of operating system.

Context Switches/Sec

The Context Switches/Sec section shows the combined rate at which all processors on the computer are switched from one thread to another. Context switches occur when a running thread voluntarily relinquishes the processor, is preempted by a higher priority ready thread, or switches between user-mode and privileged (kernel) mode to use an Executive or subsystem service.
OS View (Oracle Performance Analyst)

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > CPU Tab

Metrics  The ideal range should be between 0-10,000. GA number greater then 10,000 may indicate too many threads contending for resources.

System Calls/Sec

System calls are functions which require the services of the operating system. Usually they involve access to some data that users must not be permitted to corrupt or even change.

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > CPU Tab

Correction  Try to find a good ratio between the amount of time the operating system runs (fulfilling system calls and doing process scheduling), and the amount of time the application runs. Your goal should be running 60% to 75% of the time in application mode, and 25% to 40% of the time in operating system mode. If you find that the system is spending 50% of its time in each mode, then you should investigate to determine what is wrong.

Load Averages

The Load Average statistic represents the system load averages over the last 1, 5, and 15 minutes.

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > CPU Tab

Metrics  High load averages usually mean that the system is being used heavily and the response time is correspondingly slow.

Processes Tab

The Processes tab of the OS Detail page succinctly communicates the general overall performance levels of processes. The columns available in this table depend on the platform of operating system. The table below describes the information available in the table on this tab:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process</td>
<td>The name of the process.</td>
</tr>
<tr>
<td>User</td>
<td>The user of the process.</td>
</tr>
<tr>
<td>ID</td>
<td>The ID Process is the unique identifier of this process. ID Process numbers are reused, so they only identify a process for the lifetime of that process.</td>
</tr>
<tr>
<td>CPU</td>
<td>The CPU is the percentage of elapsed time that all of process threads used the processor to execute instructions.</td>
</tr>
<tr>
<td>User Mode</td>
<td>The User Mode is the percentage of elapsed time that the process threads spent executing code in user mode.</td>
</tr>
<tr>
<td>Memory</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory (MB)</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory</td>
<td>Memory is the percentage of the memory used of the total memory.</td>
</tr>
<tr>
<td>Active Memory</td>
<td>Active Memory is the amount of committed virtual memory, in bytes for this process. Active memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive. This counter displays the last observed value only; it is not an average.</td>
</tr>
<tr>
<td>I/O Data</td>
<td>The rate at which the process is reading and writing bytes in I/O operations. This counter counts all I/O activity generated by the process to include file, network and device I/Os.</td>
</tr>
<tr>
<td>Elapsed Time</td>
<td>The total elapsed time, in seconds, that this process has been running.</td>
</tr>
<tr>
<td>Thread Count</td>
<td>The number of threads currently active in this process. An instruction is the basic unit of execution in a processor, and a thread is the object that executes instructions. Every running process has at least one thread.</td>
</tr>
<tr>
<td>Handle Count</td>
<td>The total number of handles currently open by this process. This number is equal to the sum of the handles currently open by each thread in this process.</td>
</tr>
<tr>
<td>Priority</td>
<td>The current base priority of this process. Threads within a process can raise and lower their own base priority relative to the process' base priority.</td>
</tr>
<tr>
<td>Creating Proc ID</td>
<td>The Creating Process ID value is the Process ID of the process that created the process. The creating process may have terminated, so this value may no longer identify a running process.</td>
</tr>
</tbody>
</table>
Page Faults/Sec is the rate at which page faults by the threads executing in this process are occurring. A page fault occurs when a thread refers to a virtual memory page that is not in its working set in main memory. This may not cause the page to be fetched from disk if it is on the standby list and hence already in main memory, or if it is in use by another process with whom the page is shared.

Page File is the current number of kilobytes that this process has used in the paging file(s). Paging files are used to store pages of memory used by the process that are not contained in other files. Paging files are shared by all processes, and the lack of space in paging files can prevent other processes from allocating memory.

Private is the current size, in kilobytes, of memory that this process has allocated that cannot be shared with other processes.

I/O Tab

The sections available on this tab depend on the platform of operating system. The I/O tab includes the following sections:

- Average Disk Queue/Total Disk Queue
- Bytes per I/O Operation
- Disk I/O Time
- Disk Transfers/Sec
- I/O Details
- Transfer Rate

I/O Details

The table below describes the information available in this section:
### Column

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disk</td>
</tr>
<tr>
<td>Reading (KB/s)</td>
</tr>
<tr>
<td>Writing (KB/s)</td>
</tr>
<tr>
<td>Disk Read Time</td>
</tr>
<tr>
<td>Disk Write Time</td>
</tr>
<tr>
<td>Disk Time</td>
</tr>
<tr>
<td>Avg. Read Queue</td>
</tr>
<tr>
<td>Avg. Write Queue</td>
</tr>
<tr>
<td>Disk Reads/Sec</td>
</tr>
<tr>
<td>Disk Writes/Sec</td>
</tr>
</tbody>
</table>

**Note:** The columns available in this table depend on the platform of operating system.

### Transfer Rate

The Transfer Rate section succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading</td>
<td>The average number of bytes transferred from the disk during read operations.</td>
<td>It is measured in number of KBs per second.</td>
</tr>
<tr>
<td>Writing</td>
<td>The average number of bytes transferred to the disk during write operations.</td>
<td>It is measured in number of KBs per second.</td>
</tr>
<tr>
<td>Transferred</td>
<td>The amount of time required to transfer the data between the device’s cache and the actual device media.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.
Bytes per I/O Operation

The Bytes per I/O Operation section of the OS Detail succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading</td>
<td>The average number of bytes transferred from the disk during read operations.</td>
<td>It is measured in number of bytes per second.</td>
</tr>
<tr>
<td>Writing</td>
<td>The average number of bytes transferred to the disk during write operations.</td>
<td>It is measured in number of bytes per second.</td>
</tr>
</tbody>
</table>

Average Disk Queue/Total Disk Queue

The Average Disk Queue section of the OS Detail page succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average Read Queue</td>
<td>Average Read Queue Length is the average number of read requests that were queued for a particular disk.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system.</td>
</tr>
<tr>
<td>Average Write Queue</td>
<td>Average Write Queue is the average number of write requests that were queued for a particular disk.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system. Contact your Windows System Administrator for assistance in troubleshooting these problems.</td>
</tr>
<tr>
<td>Average Queue</td>
<td>Average time in ms. to service I/O requests which for disks includes seek, rotational latency and data transfer time).</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system. Contact your Unix System Administrator for assistance in troubleshooting these problems.</td>
</tr>
</tbody>
</table>

Note: The statistics available in this section depend on the platform of operating system.
Disk I/O Time

The Disk I/O Time section of the OS Detail page succinctly communicates the general overall performance levels of the disk’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>% Disk Read Time</td>
<td>% Disk Read Time is the percentage of time during the sample interval that the disk is busy servicing read requests.</td>
<td>Use this in conjunction with the % Disk Write Time to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
<tr>
<td>% Disk Write Time</td>
<td>% Disk Write Time is the percentage of elapsed time that the selected disk drive was busy servicing write requests.</td>
<td>Use this in conjunction with the % Disk Read Time to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
<tr>
<td>% Disk Time</td>
<td>% Disk Time is the percentage of time during the sample interval that the disk is busy servicing requests.</td>
<td>Use this statistic to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
</tbody>
</table>

Note: The statistics available in this section depend on the platform of operating system.

Disk Transfers/Sec

The Disk Transfers/Sec section of the OS Detail page succinctly communicates the general overall performance levels of the disk transfers. The table below describes the statistics in this section.
OS View (Oracle Performance Analyst)

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reads/Sec</td>
<td>The rate of read operations on the disk.</td>
</tr>
<tr>
<td>Writes/Sec</td>
<td>The rate of write operations on the disk.</td>
</tr>
<tr>
<td>Transfers/Sec</td>
<td>The rate of transfer operations per second.</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.

**Location** Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > I/O Tab

## Memory Tab

The Memory tab of the OS Detail page includes the following sections:

- **Buffer Size**
- **Cache Efficiency**
- **Cache Size**
- **Page Replacements**
- **Paging Activity**
- **Page Replacements**

The following statistic, available on this tab, duplicates a statistic available on the Bottleneck Analysis Pane of the OS View (DBArtisan - Oracle Performance Analyst) Home page:

- **Page Faults/Sec**

**Note:** The sections available on this tab depend on the platform of operating system.

## Buffer Size

The Buffer Size statistic represents the amount of cache used by the kernel in kilobytes.

**Location** Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

## Cache Efficiency

The Cache Efficiency section of the Memory tab succinctly communicates the general overall performance levels of the server's memory. The following statistics are available in this section:

- **Copy Read Hits %**
Copy Read Hits %

The Copy Read Hits % statistic is the percentage of cache copy read requests that hit the cache and does not require a disk read to provide access to the page in the cache.

**Location** Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

**Metrics** When the page is pinned in the memory, the page's physical address in the file system cache will not be altered. A copy read is a file read operation where a page in the cache is copied to the application's buffer. Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

**Correction** Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

Data Map Hits %

The Data Map Hits % statistic is the percentage of data maps in the file system cache that could be resolved without having to retrieve a page from the disk.

**Location** Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

**Metrics** Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

**Correction** Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

MDL Read Hits %

The MDL Read Hits % statistic is the percentage of Memory Descriptor List Read requests to the file system cache that hit the cache and does not require disk access to provide memory access to the pages in the cache.
Pin Read Hits %

The Pin Read Hits % statistic is the percentage of pin read requests that hit the file system cache and does not require a disk read in order to provide access to the page in the file system cache.

Cache Size

The Cache Size statistic represents the amount of cache used by the kernel in kilobytes.

Memory Available

The Memory Available section of the OS Detail page succinctly communicates the general overall performance levels of the server’s memory. The statistics available in this section depend on the platform of operating system. The table below describes these statistics:
## Physical Memory
The Physical Memory statistic is the amount of committed virtual memory, in megabytes. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Physical Memory statistic is the amount of committed virtual memory, in megabytes. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk.</td>
<td>This counter displays the last observed value only and not an average.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

## Physical
The Physical statistic is the total physical memory available.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Physical statistic is the total physical memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

## Paged Memory
The Paged Memory statistic is the amount of committed virtual memory, in bytes. Used Memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Paged Memory statistic is the amount of committed virtual memory, in bytes. Used Memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive.</td>
<td>This counter displays the last observed value only; it is not an average.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

## Swap Memory
The Swap Memory statistic is the free, unreserved swap space.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Swap Memory statistic is the free, unreserved swap space.</td>
<td>N/A</td>
<td>Increase the size of your swap file or add additional files if you consistently see a shortage of free, unreserved swap space.</td>
</tr>
</tbody>
</table>

## Swap
The Swap statistic is the total swap memory being used.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Swap statistic is the total swap memory being used.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

## Total Physical
The Total Physical statistic is the total physical memory available.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Total Physical statistic is the total physical memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

## Total Swap
The Total Swap statistic is the total swap memory available.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Total Swap statistic is the total swap memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

## Swap-ins
The number of memory pages paged in from swapspace.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The number of memory pages paged in from swapspace.</td>
<td>N/A</td>
<td>If the system is consistently low on free memory (over a 30 second average), the memory scheduler will start to swap out processes. Increase the size of your swap file or add additional files.</td>
</tr>
</tbody>
</table>

## Swap-outs
The number of memory pages paged in from swapspace.

<table>
<thead>
<tr>
<th>Description</th>
<th>Metrics</th>
<th>Troubleshooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>The number of memory pages paged in from swapspace.</td>
<td>N/A</td>
<td>If the system is consistently low on free memory (over a 30 second average), the memory scheduler will start to swap out processes. Increase the size of your swap file or add additional files.</td>
</tr>
</tbody>
</table>
Buffers | The Buffers statistic represents the amount of buffers used by the kernel in kilobytes.

Page Faults/Sec | The Page Faults/Sec statistic is the overall rate faulted pages are handled by the processor. It is measured in numbers of pages faulted per second. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults and soft faults.

This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

If the number of page faults remains consistently high, you can check with your Windows System Administrator for further investigation. Often, large numbers of page faults are not a problem so long as they are soft faults. However, hard faults, that require disk access, can cause delays.

Location: Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

Paging Activity

The Paging Activity section includes the following statistics:

- Blocks Input/Sec
- Blocks Output/Sec
- Paged In
- Paged Out
- Pages Input/Sec
- Pages Output/Sec

Note: The statistics available in this section depend on the platform of operating system.

Blocks Input/Sec

The Blocks Input/sec statistic is the number of blocks sent to a block device per second.
Correction Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Blocks Output/Sec

The Blocks Output/sec statistic is the number of blocks received from a block device per second.

Correction Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Paged In

The number of disk block paged into core from disk which occurs when the server is experiencing a shortage of RAM. Any nonzero value indicates excessive swap activity. In any virtual memory environment, it is not uncommon to see RAM pages moved out to a swap disk. This is a special disk area in UNIX that’s reserved for holding memory pages so that the processor is capable of addressing RAM in excess of its full capability. While page-out of operations are a normal part of any server’s operations, page-in operations indicate that the real amount of available RAM has been exceeded and that additional RAM pages are required on the server.

Correction High values indicate the possible need to increase the amount of RAM on the system.

Paged Out

The number of disk block paged out of core from disk. In any virtual memory environment, it is not uncommon to see RAM pages moved out to a swap disk. This is a special disk area in UNIX that’s reserved for holding memory pages so that the processor is capable of addressing RAM in excess of its full capability. While page-out of
operations are a normal part of any server’s operations, page-in operations indicate that the real amount of available RAM has been exceeded and that additional RAM pages are required on the server.

Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

Pages Input/Sec

The Pages Input/Sec statistic is the number of pages read from disk to resolve hard page faults. Hard page faults occur when a process requires code or data that is not in its working set or elsewhere in physical memory, and must be retrieved from disk.

Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

Metrics This value was designed as a primary indicator of the kinds of faults that cause system-wide delays. It includes pages retrieved to satisfy faults in the file system cache (usually requested by applications) and in non-cached mapped memory files. This counter counts numbers of pages, and can be compared to other counts of pages, such as Memory: Page Faults/sec, without conversion. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Correction Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Pages Output/Sec

The Pages Output/Sec statistic is the number of pages written to disk to free up space in physical memory. Pages are written back to disk only if they are changed in physical memory. A high rate of pages output might indicate a memory shortage.
Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

Metrics Windows NT writes more pages back to disk to free up space when low in physical memory. This counter counts numbers of pages, and can be compared to other counts of pages, without conversion. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Correction Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Page Replacements

The following statistics are available in this section:

- Memory Freed (Pages/sec)
- Clock Algorithm Scans (Pages/sec)

Memory Freed (Pages/sec)

Freed or destroyed (Kb/s).

Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

Clock Algorithm Scans (Pages/sec)

The VMM uses a technique known as the clock algorithm to select pages to be replaced. This technique takes advantage of a referenced bit for each page as an indication of what pages have been recently used (referenced). When the page-stealer routine is called, it cycles through the PFT, examining each page's referenced bit.

Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Memory Tab

Space Tab

The Space tab of the OS Detail page includes the following sections:

- Device Summary
- Device Detail
Disk Space Free

The Disk Space Free metric displays the amount of free disk space in megabytes.

Location Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Space Tab

Disk Space Detail

The Disk Space Detail section of the Space tab succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition</td>
<td>The drive letter of the disk.</td>
</tr>
<tr>
<td>Local Filesystem</td>
<td>The name of the file system.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of file system.</td>
</tr>
<tr>
<td>Total Space</td>
<td>Total size of the disk/device's capacity expressed in MBs.</td>
</tr>
<tr>
<td>Used Space</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free Space</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
<tr>
<td>Capacity</td>
<td>The percentage of space used on the device.</td>
</tr>
<tr>
<td>Mounted On</td>
<td>The mount point of the device.</td>
</tr>
</tbody>
</table>

Device Summary

The Device Summary section of the Space tab displays a bar chart for all devices. The Device Summary section succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Used</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
</tbody>
</table>
Device Detail

The Device Detail section of the Space tab succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition</td>
<td>The drive letter of the disk.</td>
</tr>
<tr>
<td>Local Filesystem</td>
<td>The name of the file system.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of file system.</td>
</tr>
<tr>
<td>Total Space</td>
<td>Total size of the disk/device's capacity expressed in MBs.</td>
</tr>
<tr>
<td>Used Space</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free Space</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
<tr>
<td>Capacity</td>
<td>The percentage of space used on the device.</td>
</tr>
<tr>
<td>Mounted On</td>
<td>The mount point of the device.</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.

Network Tab

The Network tab of the OS Detail page succinctly communicates the general overall performance levels of the server’s networking. The Network tab of the OS Detail page includes the following sections:

- Network Details
- Packet Collisions
- Packet Discards
- Packet Errors
- Transmission Rate
- Transmission Rate (Bytes)
- Transmission Queue Length
Note: The sections available on this tab depend on the platform of operating system.

Network Details

The statistics available in this section depend on the platform of operating system. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network Interface</td>
<td>The name of network interface.</td>
</tr>
<tr>
<td>INET Address/Address</td>
<td>The IP address assigned to the network interface.</td>
</tr>
<tr>
<td>Pkts Sent/Sec</td>
<td>The number of packets sent per second.</td>
</tr>
<tr>
<td>Pkts Received/Sec</td>
<td>The number of packets received per second.</td>
</tr>
<tr>

<tr>
<td>Queue Length</td>
<td>The queue length.</td>
</tr>
<tr>
<td>Collisions</td>
<td>The number of collisions.</td>
</tr>
<tr>
<td>Packets Discarded</td>
<td>The number of packets discarded.</td>
</tr>
</tbody>
</table>

Transmission Rate

The Transmission Rate section of the Network tab succinctly communicates the packet transmission rate. The following statistics are available in this section:

- Packets Received/Sec
- Packets Sent/Sec

Packets Sent/Sec

The Packets Sent/Sec statistic is the number of packets sent over each network adapter per second.
Packets Received/Sec

The Packets Received/Sec statistic is the number of packets received over each network adapter per second.

Transmission Rate (Bytes)

The Transmission Rate (Bytes) section of the Network tab succinctly communicates the packet transmission rate. The following statistics are available in this section:

- **Received (KB/Sec)**
- **Sent (KB/Sec)**

Sent (KB/Sec)

The Sent (KB/Sec) statistic is the rate at which bytes are sent over each network adapter including framing characters.

Received (KB/Sec)

The Received (KB/Sec) statistic is the rate at which bytes are received over each network adapter, including framing characters.

Transmission Queue Length

The number of pending outgoing packets on either the software transmit queue or the hardware transmit queue.
Packet Collisions

A collision occurs when two devices on the network sense that the network is idle and end up trying to send data at the same time. Some collisions are normal on a repeated network, but excess collisions can cause serious performance problems.

Correction: Contact your network administrator if there is a high rate of persistent Packet Collisions.

Packet Discards

The Packet Discards section of the Network tab succinctly communicates the packet discard rate. The following statistics are available in this section:

- Inbound Packets Discarded
- Outbound Packets Discarded
- Packet Discards

Outbound Packets Discarded

The Outbound Packets Discarded statistic is the number of outbound packets that were discarded even though no errors had been detected to prevent from being transmitted.

Correction: A possible reason for discarding such a packet could be to free up buffer space.

Inbound Packets Discarded

Received Packets Discarded is the number of received packets that were discarded even though no errors had been detected to prevent from being transmitted.

Correction: A possible reason for discarding such a packet could be to free up buffer space.
Packet Discards

The Packet Discards statistic represents the number of network packets discarded.

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Network Tab

Correction Contact your network administrator if there is high rate of persistent packet discards.

Packet Errors

The Packet Errors section of the Network tab succinctly communicates the packet error rate. The following statistics are available in this section:

- Inbound Packet Errors
- Outbound Packet Errors

Outbound Packet Errors

The Outbound Packet Errors statistic is the outbound packets that contained errors preventing them from being deliverable to a higher-layer protocol.

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Network Tab

Inbound Packet Errors

The Packets Received Errors statistic is the received packets that contained errors preventing them from being deliverable to a higher-layer protocol.

Location  Oracle Performance Analyst Statistics > OS View (DBArtisan - Oracle Performance Analyst) > Network Tab
Top SQL View (Oracle Performance Analyst)

One or two bad queries can cause a lot of trouble for the remaining sessions in a database, and so can one or two bad queries. It is important to find them before they get into a production system, but sometimes a few sneak through.

By applying custom filters and performance-related thresholds, the Top SQL view locates inefficient SQL. By applying filters to certain I/O and statistical counters, you hope to isolate queries that far exceed their nearest competitors in the same area (like disk reads). When you find them, you should reduce the number of sorts a query performs. Or, for a query that returns only a few records, you should try to minimize the number of rows a query processes.

When you begin to look for inefficient SQL in a database, there are two primary questions you need to answer:

1. What has been the worst SQL that’s historically been run in my database?
2. What is the worst SQL that’s running right now in my database?

When troubleshooting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It may be that the query is in an inefficient Transact SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.

The Top SQL view displays requested SQLOracle datasources. The following tabs are available on the Top SQL page:

- Summary
- Criteria
- SQL Details
- Recent History (Oracle 10g only)

Summary

The Summary tab of the Top SQL page includes the following sections:

- Top SQL Statements
- Top SQL Details
Top SQL View (Oracle Performance Analyst)

Top SQL Statements

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end user response times.

Before you can identify problem SQL in your database, you have to ask the question of what ‘bad SQL’ is. What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every Oracle professional’s satisfaction. The table below describes some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overall Response</td>
<td>This is how much time the query took to parse, execute, and fetch the data needed to satisfy the query. It should not include the network time needed to make the round trip from the requesting client workstation to the database server. This statistic is available in Oracle9i and later.</td>
</tr>
<tr>
<td>CPU Time</td>
<td>This is how much CPU time the query took to parse, execute, and fetch the data needed to satisfy the query.</td>
</tr>
<tr>
<td>Physical I/O</td>
<td>Often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user’s request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at a statements’ logical I/O as well.</td>
</tr>
<tr>
<td>Logical I/O</td>
<td>This number of memory reads the query took to satisfy the user’s request. The goal of tuning I/O for a query should be to examine both logical and physical I/O, and use appropriate mechanisms to keep both to a minimum.</td>
</tr>
<tr>
<td>Repetition</td>
<td>This is a measure of how often the query has been executed. A problem in this area is not as easy to spot as the others unless you know your application well. A query that takes a fraction of a second to execute may still be causing a headache on your system if it is executed erroneously (for example, a query that executes in a runaway PL/SQL loop) over and over.</td>
</tr>
</tbody>
</table>

Top SQL Details

</tbody>
</table>
Selected SQL Text

The Selected SQL Text window allows you to select any of the Top SQL result rows and get the complete SQL text. From here you can open an Explain Plan or Tune the SQL.

Recent History (Oracle 10g only)

The Recent History tab of the Top SQL view displays:

- **SQL Activity (last 24 hours)**
- **SQL Details**

SQL Activity (last 24 hours)

The SQL Activity graph shows you the resource usage of SQL statements over the last 24-hour period. You can see cumulative CPU, elapsed time, and wait time for all SQL statements that were executed during the last 24 hours.

You can also select a specific time period in the graph by drawing a box around part of the graph with your mouse. The graph will change to match your selection.

SQL Details

The SQL Details section of the Recent History view displays the SQL statements that correspond to the time period shown in the SQL Activity graph. The following columns are displayed:

- **SQL ID**: The unique identifier for the SQL statement
- **CPU Time**: The total number of CPU seconds used by the statement during the specified time period
- **CPU %**: The percentage of CPU used by the statement during the specified time period
- **Elapsed Time**: The total elapsed time for the statement (in seconds) during the specified time period
- **Elapsed %**: The percentage of elapsed time for the statement during the specified time period
Top SQL View (Oracle Performance Analyst)

- **Wait Time**: The total wait time for the statement (in seconds) during the specified time period
- **Wait %**: The percentage of wait time for the statement during the specified time period
- **SQL Time**: The total SQL execution time for the statement (in seconds) during the specified time period
- **PL/SQL Time**: The total PL/SQL execution for the statement (in seconds) during the specified time period
- **Java Time**: The total java execution time for the statement (in seconds) during the specified time period
- **Executions**: The total number of executions for the statement (in seconds) during the specified time period
- **Disk Reads**: The total number of disk reads for the statement (in seconds) during the specified time period
- **Buffer Gets**: The total number of buffer gets for the statement (in seconds) during the specified time period
- **Sorts**: The total number of sorts for the statement (in seconds) during the specified time period
- **Parse Calls**: The total number of parse calls for the statement (in seconds) during the specified time period

**Location**
- Oracle Performance Analyst Statistics > Top SQL View (DBArtisan - Oracle Performance Analyst) > Recent History (Oracle 10g only)

**Metrics**
Potential SQL tuning targets will be those statements that have unusually large amounts of CPU time, elapsed time, wait time, or number of executions.
Users View (Oracle Performance Analyst)

In addition to a Home page, the Users category of Oracle Performance Analyst includes the following tabbed pages:

- Locks/Blocking Locks Tab
- Session Waits Tab
- System Waits Tab
- Top Sessions Tab

Home

The Users home page includes the following sections:

- Bottleneck Analysis Pane
- Key User Analysis Pane
- Bottleneck Analysis Pane
- Transaction Analysis Pane
- Workload Analysis Pane

Key User Analysis Pane

User database activity can be examined using both ratio-based and wait/bottleneck-based analysis. Ratio-based analysis involves examining a number of key database ratios and statistical readings that can be used to indicate how efficiently users are accessing the database. Performance ratios serve as roll-up mechanisms for busy DBAs to use for at-a-glance performance analysis.

When using ratio-based analysis, there are some standards to adhere to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that you examine come from the v$sysstat performance view. The performance view maintains a count of all the occurrences (in the VALUE column) of a particular database incident (in the NAME column) since the database was brought up. For databases that are kept up for long periods of time, these values can grow quite large and impacts how a particular ratio is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each database’s individual ‘personality’
with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead you to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following ratios are used on the Performance Analyst Users home page to succinctly communicate the general session-based performance levels of the monitored database:

- Active Sessions
- CPU/Parse Ratio
- Inactive Sessions
- Open Cursors

The following statistics, available on this pane are duplicates of statistics available on the Key Ratio Analysis Pane of the Home View (Oracle Performance Analyst) page:

- Memory Sort Ratio
- Parse/Execute Ratio

### Active Sessions

The Active Sessions statistic is the total number of active and open threads currently reported in the database as well as the number of processes actively performing work.

**Note:** For related information, see [Active User Processes](#).

For more information, see [Inactive Sessions](#).

**Location** Oracle Performance Analyst Statistics > Users View (Oracle Performance Analyst) > Home > Key User Analysis Pane

### CPU/Parse Ratio

CPU resources are obviously required to accomplish parse activities. The CPU/Parse Ratio determines the percentage of CPU spent on user-initiated parse tasks.
Low numbers (0-5%) are desired with the CPU/parse ratio. Larger values can indicate a problem with excessive parse activity.

Correction

If you suspect an excessive parsing problem on your database, you can look into increasing the shared pool size (in hopes that SQL statements are not aged out and therefore reused) or investigate the usage of bind variable in SQL statements. If an undersized shared pool is suspected:

Increase the size of the shared_pool_size parameter through use of the ALTER SYSTEM SET shared_pool_size command value (take caution to not over-allocate; ensure enough free memory exists on server before increasing value). Monitor the new value to see if performance improves. If using an SPFILE, save the new configuration values so Oracle reuses them each time the database is stopped and re-started. If you determine that SQL literals are causing SQL to not be reused, you can:

Change the cursor_sharing parameter to FORCE by using the ALTER SYSTEM SET cursor_sharing=FORCE command. Monitor database to see if parse activity is reduced and library cache reloads shrink. If using an SPFILE, save the new configuration values so Oracle reuses them each time the database is stopped and re-started. If using an Init.ora file, add the cursor_sharing=FORCE parameter to the file.

Inactive Sessions

The Inactive Sessions statistic is the total number of threads logged on to the database that are currently idle.

Note: For related information, see Inactive User Processes.

Correction

Double-click this statistic to open the Top Sessions Tab of the Users Detail page. On this tab you can check sessions that have many seconds idle and/or that have been logged on for very long periods of time as indicated by the logon time column. After verifying that the session is no longer necessary, you can KILL the session. For more information, see Active Sessions.

Open Cursors

Open Cursors is the total number of all SQL open cursors that exist on the system. In some cases, Oracle cached cursors that have been open by PL/SQL procedures can be kept open for certain lengths of time, even though the actual activity has ceased.
You should monitor sessions to make sure that they do not approach the Open Cursor limit (specified in the Init.ora file). The parameter, open_cursors, limits how many open cursors (context areas) a session can have open at one time.

Correction If the total number of open cursors approaches the open_cursors limit then: Change the open_cursors parameter to FORCE by using the ALTER SYSTEM SET open_cursors=>'new value' command.

Bottleneck Analysis Pane

User database activity can be examined using both ratio-based and wait/bottleneck-based analysis. When connected to an Oracle database, every process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. You can use the Bottleneck Analysis section to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps you track where a database has been spending its time. If user latch contention or heavy table scan activity has been dragging a database’s performance down, you can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, you can oftentimes discover a fair amount of detail about which sessions and objects are causing the problem.

For wait event analysis to be properly carried out, it is imperative that the timed_statistics initialization parameter be set to TRUE. By default this parameter is set to FALSE, which disallows the collection of wait times for each wait event defined to the Oracle engine. For one to really understand the impact of wait events on database performance, you need to not only discover what the database is or has been waiting on, but the durations of the waits. Having both allows a complete picture to be formed regarding the magnitude of wait-initiated performance degradations. Almost all Oracle experts now agree that allowing the collection of timing statistics adds little if anything to database overhead, so setting timed_statistics to TRUE should not be a worry. The Performance Analyst Users home page identifies the current top session waits as well as the top session-related bottlenecks that have seen the most waits on the system.

When using bottleneck analysis, you cannot rely only on the information contained in the wait event views that Oracle provides. Other user-related bottlenecks include current disk sort activity. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system.

The following bottleneck indicators are used on the Performance Analyst Users home page to succinctly communicate the general overall performance level of the monitored database:
Sessions Blocked

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Although Oracle supports unlimited row-level locking, blocking lock situations do crop up. User processes holding exclusive locks and not releasing them via a proper COMMIT generally cause most blocks.

Note: This statistic is also called Current Object Blocks on the Home View (Oracle Performance Analyst) page and Session Blocks on the Objects View (Oracle Performance Analyst) Bottleneck Analysis Pane.

Location Oracle Performance Analyst Statistics > Users View (Oracle Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics You should immediately investigate any indicator above zero for a blocking lock statistic before the situation has a chance to grow out of control.

Correction Once discovered, a blocking lock situation can normally be quickly remedied. You can issue a KILL against the offending process, which eliminates the user's stranglehold on the objects they were accessing. Other user processes then nearly always complete in an instant. Embarcadero Performance Analyst makes it easier to discover the blocked lock situation, but the trick is to prevent the blocking lock situation in the first place. You can look at the Users View (Oracle Performance Analyst) detail and view all current blocking locks to see exactly which sessions are holding the currently restrictive locks. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. Most DBAs who have had to face Oracle Forms applications have suffered through the dreaded SELECT … FOR UPDATE statements that place unnecessary restrictive locks on nearly every read operation, and know all too well that good coding practice is important. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do.

Sessions in Disk Sorts

Oracle has the option of running automatic PGA memory management. Oracle has introduced a new Oracle parameter called pga_aggregate_target. When this parameter is set and you are using dedicated Oracle connections, Oracle ignores all of the PGA parameters in the Oracle file, including sort_area_size, hash_area_size and
sort_area_retained_size. Oracle recommends that the value of pga_aggregate_target be set to the amount of remaining memory (less a 10% overhead for other server tasks) on a server after the instance has been started.

The sessions in disk sorts statistic displays a count of all sessions currently performing a disk sort.

**Location**

Users View (Oracle Performance Analyst) > Oracle Performance Analyst Statistics > Users View (Oracle Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**

Consistently seeing non-zero numbers for this statistic (as well as low values observed for the memory sort ratio) can indicate excessive disk sort activity. Investigate the use of pga_aggregate_target. Once the pga_aggregate_target has been set, Oracle automatically manages PGA memory allocation, based upon the individual needs of each Oracle connection. Oracle9i or later allows the pga_aggregate_target parameter to be modified at the instance level with the alter system command, thereby lets you dynamically adjust the total RAM region available to Oracle9i. Oracle also has a parameter called workarea_size_policy. When this parameter is set to automatic, all Oracle connections benefit from the shared PGA memory. When workarea_size_policy is set to manual, connections allocate memory according to the values for the sort_area_size parameter. Under the automatic mode, Oracle tries to maximize the number of work areas that are using optimal memory and uses one-pass memory for the others.

**Correction**

If you find a problem, do the following: Edit the Init.ora or SPFILE file for the database. Increase the amount of sort_area_size to a higher value (take care not to not over-allocate; ensure enough free memory exists on server before increasing value). Realize that EVERY user receives this amount for sorting. Cycle the Oracle server when possible to allow the new value to take effect. Monitor new value to see if performance improves. In addition to increasing the amount of memory devoted to sorting, you should also locate inefficient SQL that causes needless sorts. For example, in an SQL query (to eliminate duplicate rows) UNION ALL does not cause a sort whereas UNION does. People frequently code DISTINCT inappropriately (especially people transferring from Microsoft Access, which uses DISTINCT for most SELECT queries). There are times you simply cannot stop sort activity. When this happens, you should try to keep it in memory whenever possible. However, large data warehousing systems frequently exhaust RAM sort allotments, so if disk sorts must occur, ensure three things: Your user’s TEMPORARY TABLESPACE assignment is not the SYSTEM tablespace, which is the default assignment. In Oracle9i or later, you can specify a default tablespace other than SYSTEM for every user account that is created. The TEMPORARY TABLESPACE assigned to your users is placed on a fast disk. The TEMPORARY TABLESPACE has the tablespace parameter TEMPORARY assigned to it, which allows sort activity to be performed in a more efficient manner.

**Sessions with Enqueue Waits**

An enqueue is an advanced locking device that allows multiple database processes to share certain resources. Enqueue waits typically occur when sessions wait to be granted a requested lock. Sometimes these locks are internal Oracle locks while other times they could be locks for rows of data. Note that enqueues are issued implicitly by Oracle.
Metrics

Any enqueue waits that read consistently above 1 or more (delta statistics) should be investigated.

Correction

Removing contention for enqueues is almost always an application design issue. If many enqueue waits are seen, this normally indicates either contention for certain rows in the database, or the result of database-initiated lock escalation. You should examine the use of indexes to make sure all referencing foreign keys are indexes and that SQL is tuned to not tarry over rows in the database during modification operations. Enqueue waits can also be the result of space management tasks (such as objects extending) and disk sorts (mainly in tablespaces that do not make use of the TEMPORARY tablespace parameter).

Sessions Waiting

User connections that are waiting on a system generally occur for two reasons:

1. A process waits because a requested resource is not available.
2. A process waits for Oracle to perform a prerequisite task for its given operation.

Idle waits (processes waiting because they have no work) are not usually a concern. However the two wait causes mentioned above are the ones worth your time and investigation. The sessions waiting statistic is a count of all sessions that are currently waiting for one reason or another.

Correction

If you find a problem, drill down into wait details to determine whether the waits are resource-related.

Top Bottleneck Events

When viewing wait statistics, there are many levels of detail. The first level is the system view, which provides a global, cumulative snapshot of all the waits that have occurred on a system. The second level is the session view, which shows details on which events connected sessions have experienced. Viewing these numbers can help you determine which session-related wait events have caused the most commotion in a database thus far. The Top Bottleneck Events section identifies the top waits that have occurred on the Oracle database based on the amount of time waited per event.

Correction
Appendix A in the Oracle Reference manual contains a listing and description of every current wait event defined in Oracle. DBAs unfamiliar with what each event represents should keep this listing close by as they examine wait-based event metrics. For example, a ‘db file scattered read’ event is typically indicative of table scan operations. If many of these events are observed, you should begin to see if large table scans are occurring in the database. Like the ‘db file scattered read’ event, each wait event has its own meaning and individual end-resolution diagSQL Analysis - Users

Much of a database's overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end user response times. SQL statements that use much memory can also cause a problem in a database.

Before you can identify problem SQL in your database, you have to ask the question, “What is bad SQL?” What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every Oracle professional’s satisfaction. The SQL Analysis for Users shows what SQL statements have consumed the largest percentages of executions, parse calls, CPU time, and elapsed time. The table below lists some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:
### Criteria | Description
--- | ---
Overall Response (Elapsed) Time | The amount of time the query took to parse, execute, and fetch the data needed to satisfy the query. It should not include the network time needed to make the round trip from the requesting client workstation to the database server. This statistic is available in Oracle9i or later.

CPU Time | The amount of CPU time the query took to parse, execute, and fetch the data needed to satisfy the query.

Physical I/O | This is often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user’s request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at statements’ logical I/O as well.

Logical I/O | The number of memory reads the query took to satisfy the user’s request. The goal of tuning I/O for a query should be to examine both logical and physical I/O, and use appropriate mechanisms to keep both to a minimum.

Repetition | The number of times the query has been executed. A problem in this area is not as easy to spot as the others unless you know your application well. A query that takes a fraction of a second to execute may still be causing a headache on your system if it has executed erroneously (for example, a query that executes in a runaway PL/SQL loop) over and over again.

There are other criteria that you can examine like sort activity or access plan statistics (that show items like Cartesian joins and the like), but more often than not, these measures are reflected in the criteria listed above.

Fortunately, Oracle records all the above measures (some only in 9i), which makes tracking the SQL that has been submitted against an Oracle database much easier.
Users View (Oracle Performance Analyst)

Location  Oracle Performance Analyst Statistics > Users View (Oracle Performance Analyst)  
> Home > Bottleneck Analysis Pane

Metrics When you begin to look for inefficient SQL in a database, there are two primary questions you want answered: *What HAS been the worst SQL that has historically run in my database? What IS the worst SQL that is running right now in my database?*

Correction When troubleshooting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It may be that the query is in an inefficient PL/SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint. There is the possibility that the SQL statement just is not tuned well. To determine that, you can go further into Performance Analyst’s Top SQL view and, if you have Embarcadero SQL Tuner installed, you can port the SQL over to SQL Tuner to better optimize the statement.

Transaction Analysis Pane

On a transaction-oriented system, user transactions perform COMMITs to make permanent any data additions, changes, or deletions to the database. Or they ROLLBACK any modifications to undo any work that has encountered an error or other transaction-halting situation. The transaction analysis breakdown shows current commits and rollbacks and the percentage that each activity accounts for on the database.

Metrics Large volumes of rollbacks can indicate a transaction breakdown on the system, that may need investigation at the application level.

Workload Analysis Pane

When the database population as a whole experiences a system slowdown, it is not uncommon to find one or two users who are responsible for bringing the system to its knees. In the best of worlds, users have a pretty evenly divided amount of memory usage, disk I/O, CPU utilization, and parse activity. However, users submit large batch jobs during peak OLTP activity, or when sessions that are fire off untuned queries on a critical system.

If you are seeing a slowdown in your database, and cannot seem to find a root cause, examine the resource consumption of the leading sessions on a system. A handful of users can overwhelm the I/O capabilities of Oracle (through untuned queries or runaway batch jobs) or hammer the CPU or memory structures of the database and server.

Performance Analyst makes it easy to pinpoint the top sessions by showing the leading processes at the physical I/O, logical I/O, memory, disk sort, table scan, and CPU usage levels.
Metrics If any one session uses more than 50% of a total resource (CPU, memory, etc.) go into the session to find out what they are currently executing.

Top Sessions Tab

The Top Sessions tab includes the following sections:

- Top CPU Process
- Top I/O Process
- Top Memory Process
- Top Sessions

Top I/O Process

This section identifies the Oracle process that currently has caused the most I/O usage on the database.

Location Oracle Performance Analyst Statistics > Users View (Oracle Performance Analyst) > Top Sessions Tab

Metrics To obtain more details on the top I/O process, locate the SID in the Top Sessions grid and drill down to obtain more granular information.

Top Memory Process

The Top Memory Process section identifies the Oracle process that currently is using the highest percentage of memory in the database.

Location Oracle Performance Analyst Statistics > Users View (Oracle Performance Analyst) > Top Sessions Tab

Metrics To obtain more details on the top memory process, locate the SID in the Top Sessions grid and drill down to obtain more granular information.

Top CPU Process

The Top CPU Process section identifies the Oracle process that currently has the highest percentage of CPU usage in the database.
Top Sessions

When a system experiences heavy activity, sometimes you will find that all the user connections are contributing somewhat equally to the overall load. More often than not, however, one or two user connections are causing most of the activity. It may be that a large batch load or other typical process is running that is perfectly okay for your system. Or it may be a runaway process or other rogue connection that needs to be tracked down and possibly eliminated.

The Top Sessions section displays information regarding all key metrics for all current sessions on a database. The table below describes the information available in this section:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SID</td>
<td>The system ID of the process.</td>

Metrics: To obtain more details on any process, drill down to obtain more granular information.

### System Waits Tab

The System Waits tab includes the following sections:

- [System Waits](#)
- [Wait Percent by Time Waited](#)
- [Wait Percent by Total Waits](#)

### System Waits

Waits on a system generally occur for three reasons:

1. A process waits because it has no work to do.
2. A process waits because a requested resource is not available.
3. A process waits for Oracle to perform a prerequisite task for its given operation.

Idle waits (processes waiting because they have no work) are not normally a problem, however the other two wait causes are the ones worth your time and investigation. From a global database level, there are many different types of waits and sources of contention. The system Waits section presents all the various system waits that have occurred on the system since startup. The table below lists the information available in this section:
### Users View (Oracle Performance Analyst)

<table>
<thead>

<td>The total number of timeouts for the event.</td>
</tr>
<tr>
<td>Percent Total Timeouts</td>
<td>The percentage of timeouts that this event makes up.</td>
</tr>
<tr>
<td>Average Waits (Secs)</td>
<td>The average amount of time waited for the event, in seconds.</td>
</tr>
</tbody>
</table>

**Location**

[Oracle Performance Analyst Statistics] > Users View (Oracle Performance Analyst) > System Waits Tab

**Metrics**

Which waits should be a cause for concern and which waits can be ignored (for the most part)? Common wait events that can generally be ignored include SQL*Net more data from client, SQL*Net message from client, client message, rdbms ipc message, pipe get, pmon timer, smon timer, and Null event.

**Correction**

The table below describes wait events that deserve attention:
Wait Event | Description
--- | ---
Enqueue waits | If many enqueue waits are seen, this normally indicates either contention for certain rows in the database, or the result of database-initiated lock escalation. You should examine the use of indexes to make sure all referencing foreign keys are indexes and that SQL is tuned to not tarry over rows in the database during modification operations. Enqueue waits can also be the result of space management tasks (such as objects extending) and disk sorts (mainly in tablespaces that do not make use of the TEMPORARY tablespace parameter).

Buffer busy waits | Buffer busy waits normally center around contention for rollback segments, too small an INITRANS setting for tables, or insufficient free lists for tables. The remedy for each situation would be increasing the number of rollback segments, or altering tables to have larger settings for INITRANS to allow for more transactions per data block, and more free lists.

db file scattered read waits | An interesting wait event is the db file scattered read event. This event is indicative of table scans occurring on the system. Large numbers of them may indicate heavy scan activity and the need to revisit your indexing/physical design.

Latch free waits | Latch free waits indicate contention for latches.

The SQL*Net message to client can help a DBA diagnose wait activity outside the database.

The key statistics for waits is not the number of waits for each event, but rather the wait time and average wait time. These indicate if the event is truly causing a significant bottleneck in the database. To view the wait times for sessions and overall system wait events, you must set the timed_statistics parameter to TRUE for your Oracle databases. You can either set this parameter in your Init.ora file or alter the system dynamically with the ALTER SYSTEM SET TIMED_STATISTICS=TRUE command.

**Wait Percent by Total Waits**

Waits on a system generally occur for three reasons:

- A process waits because it has no work to do.
- A process waits because a requested resource is not available.
- A process waits for Oracle to perform a prerequisite task for its given operation.

Idle waits (processes waiting because they have no work) are not normally a problem, however the other two wait causes are the ones worth your time and investigation. From a global database level, there are many different types of waits and sources of contention. The Wait Percent by Total Waits section displays the percentage of waits for all top non-idle wait events.
Which waits should be a cause for concern and which waits can be ignored (for the most part)? Common wait events that can generally be ignored include SQL*Net more data from client, SQL*Net message from client, client message, rdbms ipc message, pipe get, pmon timer, smon timer, and Null event.

The SQL*Net message to client can help a DBA diagnose wait activity outside the database.

The key statistics for waits is not the number of waits for each event, but rather the wait time and average wait time. These indicate if the event is truly causing a significant bottleneck in the database. To view the wait times for sessions and overall system waits, you must set the timed_statistics parameter to TRUE for your Oracle databases. You can either set this parameter in your Init.ora file or alter the system dynamically with the ALTER SYSTEM SET TIMED_STATISTICS=TRUE command.

**Current Waits**

Waits on a system generally occur for three reasons:

- A process waits because it has no work to do.
- A process waits because a requested resource is not available.
- A process waits for Oracle to perform a prerequisite task for its given operation.

Session contention is merely a subset of contention that is viewable at the global database level. Oftentimes, it takes analysis at the session level to pinpoint the exact source of contention that is occurring globally. So you need to become accustomed to viewing contention statistics and waits at the user process level.

When monitoring waits with respect to user sessions, there are two areas of interest:

1. What HAS the user session been waiting on?
2. What IS the user session waiting on?
Oracle records both sets of wait statistics for you. In reviewing previous waits for a session, you can see which types of things have caused the session to be bottlenecked. The Current Waits section displays information to help you troubleshoot session contention. The table below lists the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>The name of the wait event.</td>
</tr>
<tr>
<td>Wait (Secs)</td>
<td>The number of seconds in the current wait.</td>
</tr>
<tr>
<td>Last Wait Time</td>
<td>A non-zero value is the session’s last wait time. A zero value means the session is currently waiting. A -2 value indicates the platform cannot support a fast timing mechanism or TIMED_STATISTICS is not set for the system.</td>
</tr>
<tr>
<td>State</td>
<td>Indicates the possible values. They includes the following: WAITING - the session is waiting. WAITED UNKNOWN TIME - duration of last wait is not known. WAITED SHORT TIME - last wait was less than 1/100th of a second. WAITED KNOWN TIME - the wait is equal to the time of the last wait.</td>
</tr>
<tr>

**Location**  
[Oracle Performance Analyst Statistics](#) > Users View (Oracle Performance Analyst) > Locks/Blocking Locks Tab

**Metrics**  
Locks that are held for unusually long periods of time may be candidates for further investigation. The application logic may be inefficient or perhaps the program is not issuing frequent enough COMMITs.

### Blocking Locks

Without a doubt, blocking lock situations can give the appearance of a frozen database almost more than anything else (except, perhaps, for a stuck archiver process). A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Although Oracle supports unlimited row-level locking, blocking lock situations do crop up - sometimes frequently.

The Blocking Locks section contains information relating to user accounts that are currently blocked and the sessions that are blocking them. The table below describes the information available in this section:
### Column

**Blocked User**
The user account of the session waiting for the lock.

**Blocking User**
The user account of the session holding the offending lock.

**Waiting SID**
The session identifier of the session waiting for the lock.

**Holding SID**
The session identifier of the session holding the offending lock.

**Type**
The type of lock (TRANSACTION, DML, etc.).

**Mode**
The lock mode (EXCLUSIVE, SHARE, etc.).

**Request**
The type of lock being requested by the session.

**Row**
The rowid of the row being held.

**ID 1**
Lock identifier #1 (depends on type).

**ID 2**
Lock identifier #2 (depends on type).

**Time Waited (Secs)**
The amount of time, in seconds, the blocked user has been waiting.

**Locked Object**
The name of the object being locked.

---

**Location**
Oracle Performance Analyst Statistics > Users View (Oracle Performance Analyst) >
Locks/Blocking Locks Tab

**Metrics**
Once discovered, a blocking lock situation can normally be quickly remedied - the DBA issues a KILL against the offending process, which eliminates the user’s stranglehold on the objects they were accessing. Other user processes then nearly always complete in an instant. Discovering the blocked lock situation is made easier by using tools like Performance Analyst, but preventing the blocking lock situation in the first place is where it gets tricky. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. Most DBAs who have had to face Oracle Forms applications have suffered through the dreaded SELECT … FOR UPDATE statements that place unnecessary restrictive locks on nearly every read operation, and know all too well that good coding practice is important. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. Data warehouses (whose data is mostly read) can benefit from tablespaces set in READ ONLY mode. READ ONLY signals to the other database that exclusive locks need not be used for the data contained within the tablespace. This is especially helpful in Oracle Parallel Server environments and drastically reduces ping activity.
RAC Detail View (Oracle Performance Analyst)

The Performance Analyst for Oracle has been upgraded to support for the monitoring of Oracle Real Application Clustering (RAC) environments (Oracle 9i and higher).

Oracle RAC allows a single physical Oracle database to be accessed by simultaneous instances of Oracle running across several CPUs. All statistics you see are listed by instance ID.

The RAC Detail view is divided into the following tabs:

- Overview Tab
- Memory
- Ping Activity
- Locks
- Sessions

Overview

The Overview tab is of the RAC Detail view divided into the following sections:

- Key Ratio Analysis Pane
- Instance Analysis Pane
- Bottleneck Analysis Pane
- Workload Analysis Pane

Key Ratio Analysis Pane

Database performance analysts typically use one of two methods for examining the performance levels of a database: ratio-based or wait/bottleneck-based analysis. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for busy DBAs to use for at-a-glance performance analysis. Many DBAs have large database farms to contend with and can’t spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving DBAs a few solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are many opinions as to what rules to follow, there are some standards that should always be adhered to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that a DBA will examine come from the \texttt{v$sysstat}...
performance view. This view maintains a count of all the occurrences (in the VALUE column) of a particular database incident (in the NAME column) since the database was brought up. For databases that are kept up for long periods of time, these values can grow quite large and impact how a particular ratio that a DBA may be looking at is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each database’s individual “personality” with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following ratios are used on the Performance Analyst RAC Overview page to succinctly communicate the general overall performance levels of the monitored database:

- Cross Instance Cache Flush ratio
- Ping Ratio
- Local Buffer Access Percent
- Local Read Percent
- Global Buffer Busy Wait Percent

Instance Analysis Pane

As a DBA managing an Oracle RAC, you will oftentimes want a quick performance snapshot of the efficiency and activity across all your Oracle RAC nodes. The Instance Analysis section provides a fast picture of which nodes of your Oracle RAC appear overworked and those that are underutilized.

The following statistics are provided:

- **ID:** The Oracle RAC instance ID
- **Name:** The instance name
- **Sessions:** The total number of sessions logged onto a RAC node
- **Physical I/O:** A summation of all physical reads and physical writes for the RAC node
- **Logical I/O:** A summation of all logical I/O (buffer gets, consistent gets, etc.) for the RAC node
- **Hit Ratio:** An indicator of how often user requests for data are satisfied.
RAC Detail View (Oracle Performance Analyst)

- **Memory Usage**: The session’s total memory usage against all session memory usage on the database.
- **Parses**: The total number of parses experienced by the RAC node
- **Total CPU**: The total CPU usage for the RAC node
- **Parse CPU**: The amount of process CPU for the RAC node
- **Recursive CPU**: The amount of process CPU caused by recursive calls on the RAC node
- **Other CPU**: Total CPU usage minus parse and recursive activity. This can be a negative number if the Oracle kernel is not properly reporting total CPU usage
- **Disk Sorts**: The total number of disk sorts for the RAC node
- **Memory Sorts**: The total number of memory sorts for the RAC node
- **Rows Sorts**: The total number of rows sorted on the RAC node
- **Commits**: The total number of commits executed for the RAC node
- **Rollbacks**: The total number of rollbacks executed for the RAC node
- **Executions**: The total number of calls made on the RAC node
- **Physical Reads**: The total number of physical reads produced on the RAC node
- **DB Block Gets**: The total number of block gets produced on the RAC node
- **Consistent Gets**: The total number of consistent gets produced on the RAC node
- **Consistent Changes**: The total number of consistent changes produced on the RAC node

**Bottleneck Analysis Pane**

When an Oracle database is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting can mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. And this is where wait-based or bottleneck analysis comes into play. DBAs used this form of performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps a DBA track where a database has been spending its time. If latch contention or heavy table scan activity has been dragging a database’s performance down, a DBA can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, the DBA can drill down and oftentimes discover a fair amount of detail about what sessions and objects are causing the problem.
For wait event analysis to be properly carried out, it is imperative that the timed_statistics initialization parameter be set to TRUE. By default this parameter is set to FALSE, which disallows the collection of wait times for each wait event defined to the Oracle engine. For one to really understand the impact of wait events on database performance, the DBA not only needs to discover what the database is or has been waiting on, but the durations of the waits. Having both measures in hand allows a complete picture to be formed regarding the magnitude of wait-initiated performance degradations. Almost all Oracle experts now agree that allowing the collection of timing statistics adds little if anything to database overhead, so setting timed_statistics to TRUE should not be a worry. The Performance Analyst home page identifies the top system and session waits that are currently a cause of lessened performance.

When using bottleneck analysis, you cannot rely only on information contained in the wait event views that Oracle provides. For example, an object may attempt to extend into another extent of space in a tablespace and yet be denied if no such free space exists. Such a failure will not be reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that you cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain an accurate performance risk assessment. Performance Analyst helps identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system.

For an Oracle RAC, Performance Analyst highlights the top RAC-related waits as well as conflicts that may be slowing down response times. Here you see statistics for Top Rac-Related Waits and Conflicts. Within each section, you find:

**Top Rac-Related Waits**

When viewing wait statistics, there are several levels of detail that a DBA can drill down into. The first level is the system view, which provides a global, cumulative snapshot of all the waits that have occurred on a system. Viewing these numbers can help a DBA determine what wait events have caused the most commotion in a database thus far. The Top RAC-related bottlenecks section display identifies the top waits that have occurred on the node that Performance Analyst is currently connected to.

Appendix A in the Oracle Reference manual contains a listing and description of every current wait event defined in Oracle. DBAs unfamiliar with what each event represents should keep this listing close by as they examine wait-based event metrics. For example, a “db file scattered read” event is typically indicative of table scan operations. If many of these events are observed, then the DBA should begin to see if large table scans are occurring in the database. Like the “db file scattered read” event, each wait event has its own meaning and individual end-resolution diagnosis.

After looking at system-level wait activity, a DBA can drill down further to discover what current connections may be responsible for any reported waits that are being observed at the system level. Performance Analyst reports on historical and current wait events at the session level, making this investigation easy to accomplish.

**Conflicts**
There are a number of conflicts that can occur over an Oracle RAC that can reduce response times. The Conflicts section highlights some of the more common conflicts and provides a count of how many times each has occurred.

The conflicts listed include:

- **Library Cache**: How many library cache invalidations have occurred on the node that Performance Analyst is connected to.
- **Data Dictionary Cache**: How many data dictionary cache invalidations have occurred on the node that Performance Analyst is connected to.
- **Forced Writes (Oracle 9.2 and above)**: Number of times a block was written to cache because an instance had used the block, but another instance had requested the lock on the block in a conflicting mode.
- **Pings**: How many cross instance writes occurred
- **Cache Timeouts**: The number of global cache convert timeouts that have occurred.

**Workload Analysis Pane**

When your phone starts ringing with complaints of performance slowdowns, one of the first things you should get a handle on is:

- Who is currently connected to the database
- What resources are they using
- What are they currently executing

The Workload Activity Analysis section of the Performance Analyst home page provides insight into the leading resource hogs across all instances of an Oracle RAC. Drill down's are available so you can easily get detailed information into what each leading session is currently involved with.

If you are seeing a slowdown in your database, and can't seem to find a root cause, one thing to examine is the resource consumption of the leading sessions on a system. Often you will find one or a handful of users making life miserable for everyone else. They accomplish this by overwhelming the I/O capabilities of Oracle (through untuned queries or runaway batch jobs) or hammering the CPU or memory structures of the database and server.

The Workload Analysis section presents:

- Top Physical I/O Process
- Top Logical I/O Process
- Top Memory Process
- Top CPU Process
For each of these, you see the SID, Instance ID, Username, %Used.

If any one session appears to be using more than 50% of a total resource (CPU, memory, etc.), then you should drill down into the session to find out what it is currently executing.

**Memory**

The Memory tab of the RAC Detail view is divided into the following sections:

- Key Ratio Analysis Pane
- Memory Analysis Pane
- Library Cache Analysis Pane
- Data Dictionary Cache Analysis Pane

**Key Ratio Analysis Pane**

Database performance analysts typically use one of two methods for examining the performance levels of a database: Ratio-based or wait/bottleneck-based analysis. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for busy DBAs to use for at-a-glance performance analysis. Many DBAs have large database farms to contend with and can’t spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving DBAs a few solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are many opinions as to what rules to follow, there are some standards that should always be adhered to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that a DBA examines come from the `v$sysstat` performance view. This view maintains a count of all the occurrences (in the VALUE column) of a particular database incident (in the NAME column) since the database was brought up. For databases that are kept up for long periods of time, these values can grow quite large and will impact how a particular ratio that a DBA may be looking at is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each database’s individual “personality” with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.
The following ratios are used in the Memory Key Ratio Analysis section to succinctly communicate the general overall performance levels of the monitored database:

- **Buffer Cache Hit Ratio**: How often requested information is found in memory versus on disk.
- **Library Cache Hit Ratio**: Shows how often SQL code is being reused by other database users versus the number of times a SQL statement is broken down, parsed, and then loaded (or reloaded) into the shared pool.
- **Latch Miss Ratio**: Defines the number of times a process obtained a willing-to-wait latch versus missing the attempt.

### Memory Analysis Pane

The Memory Analysis section displays the memory configurations for each node currently up in the RAC. The following information is shown:

**Name**: The name of the instance.

- **DB Buffers (MB)**: The default memory cache that maintains data blocks when they are read from the database. If the DBA doesn’t specifically place objects in another data cache (which will be covered next), then any data requested by clients from the database will be placed into this cache. This memory area is controlled by the `b_cache_size` parameter.
- **Log Buffer Size (MB)**: This area buffers modifications that are made to the database before they are physically written to the redo log files. The `log_buffer` configuration parameter controls this memory area.
- **Shared Pool Size (MB)**: This familiar area holds object structure as well as code definitions, and other metadata. Setting the proper amount of memory in the shared pool assists a great deal in improving overall performance with respect to code execution.
- **DB Caches (MB)**: Beginning in Oracle9i, a DBA can create tablespaces whose blocksize differs from the overall database blocksize. When data is read into the SGA from these tablespaces, their data has to be placed into memory regions that can accommodate their special block size. Oracle9i and above has memory settings for 2K, 4K, 8K, 16K, and 32K caches. The configuration parameter names are in the pattern of `db_nk_cache_size`. For each RAC node, you see the following statistics:
  - Buffer Cache Hit Ratio
  - Library Cache Hit Ratio
  - Latch Miss Ratio
Library Cache Analysis Pane

The Library Cache Analysis section provides a drill down view into invalidations that have occurred across the cluster. The following information is shown:

- **ID**: The instance ID.
- **Name**: The instance name.
- **Namespace**: The area of the library cache.
- **DLM Lock Requests**: The number of get requests for instance locks.
- **DLM Pin Requests**: The number of pin requests for instance locks.
- **DLM Pin Releases**: The number of release requests for pin instance locks.
- **DLM Invalidation Requests**: The number of get requests for invalidation instance locks.
- **DLM Invalidations**: The number of invalidation pings received from other RAC instances.

Data Dictionary Cache Analysis Pane

The Data Dictionary Cache Analysis section provides a drill-down view into invalidations and conflicts that have occurred across the cluster. The following information is shown:

- **ID**: The instance ID.
- **Name**: The instance name.
- **Parameter**: The specific object area of the dictionary cache.
- **DLM Requests**: The number of lock manager requests.
- **DLM Conflicts**: The number of lock manager conflicts encountered.
- **DLM Releases**: The number of lock manager releases.

Ping Activity

Pinging is the process where one Oracle Instance requests another to write a set of blocks from its SGA to disk so it can obtain it in exclusive mode. To move a data block from one instance’s SGA to another is a slow process. The Ping Activity tab of the RAC Detail view displays several levels of specificity, starting from general to specific. The Ping Activity tab is divided into the following sections:

**Ping by Instance** - shows how often pinging has occurred across all the monitored instances.

**Ping by Datafile** - shows the number of blocks pinged from the shared set of RAC datafiles.
Ping by Object - provides a drill down view into the amount of specific ping activity across the shared objects and datafiles of a RAC:

- Owner
- Object Name
- Partition Name
- Block Number
- Segment Type
- Kind
- Forced Reads
- Forced Writes
- Datafile

Locks

The Locks tab of the RAC Detail view is divided into the following sections:

Lock Convert Summary - The Lock Convert Summary view provides efficiency statistics regarding the speed at which the RAC acquires and converts locks across the instances. You see the average get and convert times for each RAC node.

DLM Lock Activity - The DLM (Distributed Lock Manager) Lock Activity view provides detailed information on the number of lock conversions that have occurred across the RAC.

PCM Lock Summary - The PCM (Parallel Cache Management) Lock Summary provides a summary count of PCM locks that are releasing, acquiring, or are invalid.

Latch Detail - Protecting the memory structures in Oracle's SGA are latches. Latches ensure that one and only one process at a time can run or modify any memory structure at the same instant. Much more restrictive than locks (which at least allow for some collective user interaction), latches have no queuing mechanism so either you get it or you don’t and are forced to continually retry.

The latch detail tab of the contention detail view presents a detailed view of latch activity. Information presented includes:

- Instance Name: The name of the instance
- Name: The name of the latch
- Gets: The total number of times the latch was requested by a process
- Misses: The total number of failed attempts to acquire the latch on the first attempt
- Immediate Gets: The total number of no-wait requests for a latch
Immediate Misses: The total number of failed no-wait attempts to acquire the latch on the first attempt

Immediate Sleeps: The total number of requests that "paused" while waiting for a latch

Common indicators of latch contention are a latch miss ratio (which records willing-to-wait mode latch requests) and a latch immediate miss ratio (which records no-wait mode latch requests). These statistics reflect the overall health of how often latch requests were made and satisfied without waiting.

Here are a few latch contention situations that you should recognize and get to the bottom of quickly:

- Cache buffer chain latch: This latch is responsible for protecting paths to database block buffers in the buffer cache. Very high I/O loads tend to cause contention for this latch. You can alleviate contention somewhat by adding more buffers to the cache (through the `db_block_buffers` parameter) or by adding more LRU latch chain latches with the `db_block_lru_latches` parameter.

- Library cache latches: Protects cached SQL statements in the library cache area of the Oracle shared pool. Contention for this latch is the usual result of literals being used for SQL statements instead of bind variables.

Sessions

The Sessions tab of the RAC Detail view is divided into the following sections:

User Session by Instance - The User Session by Instance section provides a graphical count of the number of connected sessions for each node in the RAC.

Blocks by Instance - The Blocks by Instance section provides a graphical count of the number of blocked sessions for each node in the RAC.

User Waits by Instance - The User Waits by Instance section provides a graphical count of the number of historical session waits (non-idle) for each node in the RAC.

Top Sessions - When a system experiences heavy activity, sometimes you’ll find that all the user connections are contributing somewhat equally to the overall load. Often, however, one or two user connections are causing most of the activity. It may be that a large batch load or other typical process is running that is perfectly OK for your system. Or it may be a runaway process or other rogue connection that needs to be tracked down and possibly eliminated.

The top sessions control displays information regarding all key metrics for all current sessions on a database. Information presented includes:

- SID: The system ID of the process
- Instance: The instance the session is connected to
- Username: The username of the process
- **O/S ID**: The operating system ID of the process
- **Machine Name**: The workstation where the process originated
- **Logon Time**: The date/time the process logged on to Oracle
- **Tot Physical I/O**: A summation of all physical reads and physical writes for the process (includes direct)
- **Tot Physical I/O**: A summation of all logical I/O (buffer gets, consistent gets, etc.) for the process
- **Parses**: The total number of parses the process has caused
- **Total CPU**: The total CPU usage for the process
- **Parse CPU**: The amount of process CPU caused by parse activity
- **Recursive CPU**: The amount of process CPU caused by recursive calls
- **Other CPU**: Total CPU usage minus parse and recursive activity. This can be a negative number if the Oracle kernel is not properly reporting total CPU usage
- **Disk sorts**: The total number of disk sorts caused by the process
- **Memory sorts**: The total number of memory sorts caused by the process
- **Rows sorted**: The total number of rows sorted by the process
- **Commits**: The total number of commits executed by the process
- **Rollbacks**: The total number of rollbacks executed by the process
- **Physical reads**: The total number of physical reads produced by the process
- **DB block gets**: The total number of block gets produced by the process
- **Consistent gets**: The total number of consistent gets produced by the process
- **Consistent changes**: The total number of consistent changes produced by the process
Response Time Analysis View (Oracle 10G Only)

The Response Time Analysis View displays statistics that are a part of the Oracle 10g wait enhancements. By analyzing response times, you can review historical data and pinpoint who was on a database and what they were doing during a specific period of time. This allows you to drill deep into the root causes, if any of response time problems, up to 24 hours after the fact.

The main Response Time Analysis View displays the following tabbed pages:

- Response Time
- Active Time
- System Bottlenecks
- Session Bottlenecks
- Wait Histogram
- Historical Session Analysis

Response Time

The Response Time tab of the Response Time Analysis View displays the following statistics:

- Current Workload
- Current Response Times
- Last Hour
- Last Hour Detail

Current Workload

The Current Workload section provides a breakdown of active and idle time for the Oracle database engine in terms of percentage used.
Response Time Analysis View (Oracle 10G Only)

Location Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > Response Time

Metrics Seeing consistently high percentages for the Database CPU Time (greater than 75-90%) should indicate a possibly overworked server.

Correction If you see high numbers for the Database CPU Time, then begin looking into these statistics: SQL Statements with high elapsed times and CPU times (use the Top SQL view to find these). Sessions with high wait times (especially in the User I/O wait class).

Current Response Times

The Current Response Times section provides a quick view into the current average response time that a transaction experiences on the system along with the current average SQL service time. Both statistics are expressed in seconds.

Location Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > Response Time

Metrics Defining ‘good’ and ‘bad’ metrics for these two measurements can only be accomplished by viewing these statistics over time and determining what ‘normal’ is for your system. You can get help by checking the Last Hour section, which details the minimum, maximum, and average values for these statistics as well as other key metrics that provide insight into how well your database is running.

Last Hour

The Last Hour section provides a window into various key performance metrics. Each metric’s minimum, maximum, and average value is displayed.

Location Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > Response Time

Metrics Key metrics to keep an eye on include: CPU usage per Txn, Database CPU Time Ratio, Response Time Per Txn, and SQL Service Response Time.

Correction If you see high numbers for the Database CPU Time, then begin looking into these statistics: SQL Statements with high elapsed times and CPU times (use the Top SQL view to find these). Sessions with high wait times (especially in the User I/O wait class).

Last Hour Detail

The Last Hour Detail section provides a graphical look back over the last hour of a selected performance metric. Oracle10g and higher automatically maintains a running history of selected metrics so you can observe trends and patterns in performance.
Active Time

The Active Time tab of the Response Time Analysis detail view displays the following statistics:

- System Time Summary
- System Time Detail
- Session Time Detail

System Time Summary

The System Time Summary section allows you to see where, in broad terms, the database engine has been spending the largest percentages of its time.

Location Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > Active Time

Metrics

The metrics shown here include (note, this table is largely from Oracle 10g documentation):
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Time</td>
<td>You see the amount of elapsed time (in microseconds) spent performing Database user-level calls. Instance background processes such as PMON are not included.</td>
</tr>
<tr>
<td>DB CPU</td>
<td>Amount of CPU time (in microseconds) spent on database user-level calls. Instance background processes such as PMON are not included.</td>
</tr>
<tr>
<td>background cpu time</td>
<td>Amount of CPU time (in microseconds) taken up by database background processes.</td>
</tr>
<tr>
<td>sequence load elapsed time</td>
<td>Amount of elapsed time spent getting the next sequence number from the data dictionary. If a sequence is cached, then this is the amount of time spent replenishing the cache when it runs out. No time is charged when a sequence number is found in the cache. For non-cached sequences, some time is charged for every nextval call.</td>
</tr>
<tr>
<td>parse time elapsed</td>
<td>Amount of elapsed time spent parsing SQL statements. Both soft and hard parse times are included.</td>
</tr>
<tr>
<td>hard parse elapsed time</td>
<td>Amount of elapsed time spent hard parsing SQL statements.</td>
</tr>
<tr>
<td>sql execute elapsed time</td>
<td>Amount of elapsed time SQL statements are executing. NOTE: For select statements this also includes the amount of time spent performing fetches of query results.</td>
</tr>
<tr>
<td>connection management call elapsed time</td>
<td>Amount of elapsed time spent performing session connect and disconnect calls.</td>
</tr>
<tr>
<td>failed parse elapsed time</td>
<td>Amount of time spent performing SQL parses that ultimately fail with some parse error.</td>
</tr>
<tr>
<td>hard parse elapsed time (sharing criteria)</td>
<td>Amount of elapsed time spent performing SQL hard parses when the hard parse resulted from not being able to share an existing cursor in the SQL cache.</td>
</tr>
<tr>
<td>hard parse elapsed time (bind mismatch)</td>
<td>Amount of elapsed time spent performing SQL hard parses when the hard parse resulted from bind type or bind size mismatch with an existing cursor in the SQL cache.</td>
</tr>
<tr>
<td>PL/SQL execution elapsed time</td>
<td>Amount of elapsed time spent running the PL/SQL interpreter. This does not include time spent recursively executing/parsing SQL statements or time spent recursively executing the Java VM.</td>
</tr>
<tr>
<td>PL/SQL compilation elapsed time</td>
<td>Amount of elapsed time spent running the PL/SQL compiler.</td>
</tr>
<tr>
<td>inbound PL/SQL rpc elapsed time</td>
<td>Time inbound PL/SQL remote procedure calls have spent executing. It includes all time spent recursively executing SQL and JAVA, and therefore is not easily related to &quot;PL/SQL execution elapsed time&quot;.</td>
</tr>
</tbody>
</table>
Java execution elapsed time

Amount of elapsed time spent running the Java VM. This does not include time spent recursively executing/parsing SQL statements or time spent recursively executing PL/SQL.

System Time Detail

The System Time Detail section allows you to see where the database engine has been spending its time. Both raw time and percentage of total metrics are included.

Metric

The metrics shown here include (note, this table is largely from Oracle 10g documentation):
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Time</td>
<td>Amount of elapsed time (in microseconds) spent performing Database user-level calls. This does not include the time spent on instance background processes such as PMON.</td>
</tr>
<tr>
<td>DB CPU</td>
<td>Amount of CPU time (in microseconds) spent on database user-level calls. This does not include the CPU time spent on instance background processes such as PMON.</td>
</tr>
<tr>
<td>background cpu time</td>
<td>Amount of CPU time (in microseconds) consumed by database background processes.</td>
</tr>
<tr>
<td>sequence load elapsed time</td>
<td>Amount of elapsed time spent getting the next sequence number from the data dictionary. If a sequence is cached, then this is the amount of time spent replenishing the cache when it runs out. No time is charged when a sequence number is found in the cache. For non-cached sequences, some time will be charged for every nextval call.</td>
</tr>
<tr>
<td>parse time elapsed</td>
<td>Amount of elapsed time spent parsing SQL statements. It includes both soft and hard parse time.</td>
</tr>
<tr>
<td>hard parse elapsed</td>
<td>Amount of elapsed time spent hard parsing SQL statements.</td>
</tr>
<tr>
<td>sql execute elapsed time</td>
<td>Amount of elapsed time SQL statements are executing. Note that for select statements this also includes the amount of time spent performing fetches of query results.</td>
</tr>
<tr>
<td>connection management call elapsed time</td>
<td>Amount of elapsed time spent performing session connect and disconnect calls.</td>
</tr>
<tr>
<td>failed parse elapsed time</td>
<td>Amount of time spent performing SQL parses which ultimately fail with some parse error.</td>
</tr>
<tr>
<td>hard parse (sharing criteria) elapsed time</td>
<td>Amount of elapsed time spent performing SQL hard parses when the hard parse resulted from not being able to share an existing cursor in the SQL cache.</td>
</tr>
<tr>
<td>hard parse (bind mismatch) elapsed time</td>
<td>Amount of elapsed time spent performing SQL hard parses when the hard parse resulted from bind type or bind size mismatch with an existing cursor in the SQL cache.</td>
</tr>
<tr>
<td>PL/SQL execution elapsed time</td>
<td>Amount of elapsed time spent running the PL/SQL interpreter. This does not include time spent recursively executing/parsing SQL statements or time spent recursively executing the Java VM.</td>
</tr>
<tr>
<td>PL/SQL compilation elapsed time</td>
<td>Amount of elapsed time spent running the PL/SQL compiler.</td>
</tr>
</tbody>
</table>
inbound PL/SQL rpc elapsed time
Time inbound PL/SQL remote procedure calls have spent executing. It includes all time spent recursively executing SQL and JAVA, and therefore is not easily related to "PL/SQL execution elapsed time".

Java execution elapsed time
Amount of elapsed time spent running the Java VM. This does not include time spent recursively executing/parsing SQL statements or time spent recursively executing PL/SQL.

Session Time Detail
This section allows you to see where sessions that are currently logged on are spending their time.

Location Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > Active Time

</tr>
<tr>
<td>PL/SQL execution elapsed time</td>
<td>Amount of elapsed time spent running the PL/SQL interpreter. This does not include time spent recursively executing/parsing SQL statements or time spent recursively executing the Java VM.</td>
</tr>
<tr>
<td>PL/SQL compilation elapsed time</td>
<td>Amount of elapsed time spent running the PL/SQL compiler.</td>
</tr>
</tbody>
</table>
Response Time Analysis View (Oracle 10G Only)

inbound PL/SQL rpc elapsed time

Time inbound PL/SQL remote procedure calls have spent executing. It includes all time spent recursively executing SQL and JAVA, and therefore is not easily related to "PL/SQL execution elapsed time".

Java execution elapsed time

Amount of elapsed time spent running the Java VM. This does not include time spent recursively executing/parsing SQL statements or time spent recursively executing PL/SQL.

System Bottlenecks

The System Bottlenecks tab of the Response Time Analyst detail view displays the following information:

- Bottleneck Summary
- Bottleneck Detail
- Bottleneck History (One Hour)

Bottleneck Summary

Waits on a system generally occur for three reasons:

1. A process waits because it has no work to do.
2. A process waits because a requested resource is not available.
3. A process waits for Oracle to perform a prerequisite task for its given operation.

Idle waits (processes waiting because they have no work) are not normally a problem, however the other two wait causes are the ones worth your time and investigation. From a global database level, there are many different types of waits and sources of contention. The Bottleneck Summary section presents the broad categories of waits (called classes) so you can see if, for example, User I/O is causing high wait times. The percentage of each wait class is shown in the pie chart.

Location Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > System Bottlenecks

Metrics Details can be viewed for the wait classes by drilling down into the System Waits view.

Bottleneck Detail

Waits on a system generally occur for one of three reasons:

1. A process waits because it has no work to do.
2. A process waits because a requested resource is not available.
3. A process waits for Oracle to perform a prerequisite task for its given operation.
Idle waits (processes waiting because they have no work) are not normally a problem, however the other two wait causes are the ones worth your time and investigation. From a global database level, there are many different types of waits and sources of contention. The Bottleneck Detail section presents the broad categories of waits (called classes) so you can see if, for example, User I/O is causing high wait times. The wait class, total waits, percentage of total waits, wait time (in seconds) and percentage of wait time is shown. Note that all these metrics are cumulative since the instance was started.

Location: Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > System Bottlenecks

Metrics
Details can be viewed for the wait classes by drilling down into the System Waits view.

Bottleneck History (One Hour)

Waits on a system generally occur for three reasons:

1. A process waits because it has no work to do.
2. A process waits because a requested resource is not available.
3. A process waits for Oracle to perform a prerequisite task for its given operation.

Idle waits (processes waiting because they have no work) are not normally a problem, however the other two wait causes are the ones worth your time and investigation. From a global database level, there are many different types of waits and sources of contention.

The Bottleneck History section allows you to view wait counts, wait time, or a count of user sessions waiting over the past hour for all the specific wait classes (User I/O, System I/O, etc.)

Location: Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > System Bottlenecks

Session Bottlenecks

The Session Bottlenecks tab of the Response Time Analysis detail view displays the following information:

- Session Bottleneck Summary
- Session Bottleneck Detail
- Session Wait History (One Hour)

Session Bottleneck Summary

Waits on a system generally occur for three reasons:
1. A process waits because it has no work to do.
2. A process waits because a requested resource is not available.
3. A process waits for Oracle to perform a prerequisite task for its given operation.

Idle waits (processes waiting because they have no work) are not normally a problem, however the other two wait causes are the ones worth your time and investigation. From a global database level, there are many different types of waits and sources of contention.

The Session Bottleneck Summary section shows where currently logged on sessions have been spending the largest percentages of their time (over broad wait classes).

Location Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > Session Bottlenecks

Metrics To view the actual wait events that comprise the highest percentages of time viewed in each wait class, drill down into the Session Waits view.

Session Bottleneck Detail

Waits on a system generally occur for three reasons:

1. A process waits because it has no work to do.
2. A process waits because a requested resource is not available.
3. A process waits for Oracle to perform a prerequisite task for its given operation.

Idle waits (processes waiting because they have no work) are not normally a problem, however the other two wait causes are the ones worth your time and investigation. From a global database level, there are many different types of waits and sources of contention.

The Session Bottleneck Detail section shows where currently logged on sessions have been spending the largest percentages of their time (over broad wait classes). Each session is shown along with its SID, user name, wait class, total waits, time waited (in seconds), and percent of total time.

Location Oracle Performance Analyst Statistics > Response Time Analysis View (Oracle 10G Only) > Session Bottlenecks

Metrics To view the actual wait events that comprise the highest wait times/percentages of time viewed in each wait class, drill down into the Session Waits view.

Session Wait History (One Hour)

The Session Wait History allows you to look back over the last hour to see when sessions where waiting, how many waits occurred, and the amount of wait time associated during a specific period of time. Analyzing such data over time will give you an idea of how often waits are occurring and their overall impact on system performance.
Wait Histogram

The Wait Histogram view allows you to view a histogram of wait times and wait counts for a variety of wait events. Using the wait histogram view, you can see, for example, that a db file scattered read event had 20 waits that took an average of 1 second and 10 waits that took an average of 2 seconds, and so on. This allows you to get a better idea of the actual impact of various wait events than viewing broad percentages or averages.

Historical Session Analysis

The Historical Session Analysis tab of the Response Time Analysis detail view shows data for:

- Historical Session Analysis
- Historical Session Analysis Detail - All Waits

Historical Session Analysis

Oracle10g and above allow you to review various historical performance metrics for your database. The Historical Analysis graph allows you to input a time period and review wait times to see when your server experienced high volumes of wait activity. You can choose to look at global wait classes or specific waits events for wait classes.

You can also select a specific time period in the graph by drawing a box around part of the graph with your mouse. The graph will change to match your selection.

Historical Session Analysis Detail - All Waits

Oracle10g and above allows you to review various historical performance metrics for your database. The Historical Analysis Detail section allows you to review specific details regarding times when your database server experienced unacceptable wait times. You can review historical response time data for sessions, SQL statements, files, and objects.

This section allows you, for example, to see what wait events long running SQL statements experienced and what objects caused excessive wait times.
Session Details View (Oracle Performance Analyst)

The following tabbed pages are available on the Session Details page:

- **Current Work Tab**
- **Locks Tab**
- **Overview Tab**
- **SQL Tab**
- **Waits Tab**

### Overview Tab

Several sections are available on the Overview tab of the Session Details page. The table below describes the sections:

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory Usage</td>
<td>The Memory Usage section defines the session's total memory usage against all session memory usage on the database.</td>
</tr>
<tr>
<td>I/O Activity</td>
<td>The I/O section defines the session's total I/O consumption against all I/O activity on the database. NOTE Bugs in some versions of the Oracle data dictionary cause negative numbers to display if the database has experienced large amounts of I/O activity.</td>
</tr>
<tr>
<td>CPU Activity</td>
<td>The CPU Activity section defines the session's total CPU consumption against all CPU usage on the database. NOTE Bugs in some versions of the Oracle data dictionary cause the total CPU usage for a session to not be calculated correctly.</td>
</tr>
<tr>
<td>Statistical Detail</td>
<td>The Statistical Detail section details every performance metric available for the session. NOTE Each measure continue to increment as long as the session stays connected to Oracle.</td>
</tr>
</tbody>
</table>

### Current Work Tab

The Current Work tab of the Session Details page includes the following sections:

- **Open Transactions**

The following statistic, available on this tab, duplicates a statistic available on the **Key User Analysis Pane**:

- **Open Cursors**
Open Transactions

This Open Transactions section displays details regarding any open transaction that the session currently has. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Text</td>
<td>The SQL that contains the transaction.</td>
</tr>
<tr>
<td>Start Time</td>
<td>The time the statement was issued.</td>
</tr>
<tr>
<td>Logical I/O</td>
<td>The amount of memory I/O the transaction has used.</td>
</tr>
<tr>
<td>Physical I/O</td>
<td>The amount of disk I/O the transaction has used.</td>
</tr>
<tr>
<td>Gets</td>
<td>A subset of logical I/O.</td>
</tr>
<tr>
<td>Changes</td>
<td>Any data modifications made by the transaction.</td>
</tr>
</tbody>
</table>

Metric

Seeing a long running, persistent transaction might indicate a session caught in a loop or other coding snafu. Watching a transaction sit idle could clue you into a lock contention problem that exists.

Waits Tab

The Waits tab of the Session Details page includes the following sections:

- Time Summary (Oracle 10g only)
- Last Ten Waits (Oracle 10g only)

The following statistics, available on this tab, are duplicates of statistics available on the System Waits Tab of the Users View (Oracle Performance Analyst) page:

- Historical Waits
- Current Waits

Time Summary (Oracle 10g only)

The Time Summary section shows you where the session has been spending its time. Using the Time Summary section, you can easily determine if a session has been bottlenecked by SQL calls, PL/SQL work, or other activities.
Last Ten Waits (Oracle 10g only)

The Last Ten Waits section shows you, in order, the last 10 wait events experienced by the session, along with other important metrics like the wait time, and so forth.

Locks Tab

The following statistics, available on this tab, are duplicates of statistics available on the Locks/Blocking Locks Tab of the Users View (Oracle Performance Analyst) page:
- All Locks
- Blocking Locks

SQL Tab

The SQL tab of the Session Details page includes the following sections:
- Current SQL
- Current SQL Statistics
- Other SQL

Current SQL

The Current SQL section displays the most current SQL issued by the session.

Note: You can run an EXPLAIN PLAN on the SQL or (if you have Embarcadero SQL Tuner installed) tune the SQL for better performance.

Current SQL Statistics

The Current SQL Statistics section displays the performance execution metrics for the current SQL statement in graphical format. Physical and logical I/O is displayed along with rows processed and number of executions.
Other SQL

The Other SQL section displays other SQL that has been parsed by the Oracle username. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Text</td>
<td>A snippet of the SQL code issued.</td>
</tr>
<tr>
<td>Disk Reads</td>
<td>The number of total disk reads for the statement.</td>
</tr>
<tr>
<td>Buffer Gets</td>
<td>The number of total buffer gets for the statement.</td>
</tr>
<tr>
<td>Rows Processed</td>
<td>The number of total rows processed for the statement.</td>
</tr>
<tr>
<td>Executions</td>
<td>The number of times the statement has been executed.</td>
</tr>
<tr>
<td>Sorts</td>
<td>The number of sorts for the statement.</td>
</tr>
</tbody>
</table>

Note: Bugs in some versions of Oracle will cause negative numbers to display for various execution metrics.
Performance Analyst for Microsoft SQL Server Tutorial

Embarcadero Performance Analyst provides key insight into the complex world of database performance. Running inside the Embarcadero DBArtisan console, or standalone in a Web browser, Performance Analyst helps you pinpoint performance problems that threaten a database’s availability or response times. The powerful analysis facilities will satisfy advanced experts, yet novices will find Performance Analyst’s interface easy to use and the expert help a welcome aid to troubleshooting difficult performance issues.

Proceed to About This Performance Analyst for Microsoft Tutorial

Topics

- About This Performance Analyst for Microsoft Tutorial
- Session 1: Getting Started with Performance Analyst for Microsoft
- Session 2: Using Ratio-based Performance Analysis in Performance Analyst for Microsoft
- Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Microsoft
- Session 4: Using Workload Performance Analysis in Performance Analyst for Microsoft
- Session 5: Using SQL Performance Analysis in Performance Analyst for Microsoft
- Session 6: Using Operating System Performance Analysis in Performance Analyst for Microsoft
- Session 7: Identifying and Getting Help With Performance Problems Using Performance Analyst for Microsoft
- Session 8: Fixing Identified Problems Using Performance Analyst for Microsoft
About This Performance Analyst for Microsoft Tutorial

This tutorial is intended to help you get started with Embarcadero Performance Analyst.

After completing this tutorial, you will have the foundation you need to explore the many features and benefits of Performance Analyst. You will have learned how to accurately monitor your database using the most popular performance methodologies in use today. You will know how to drill down into the many layers of database performance and also be able to locate performance issues in your database in a fast and effective manner. Finally, you’ll understand how to fix performance problems using the integration that exists between Performance Analyst and Embarcadero DBArtisan.

This tutorial is divided into 8 sections.

- **Session 1**: Getting Started with Performance Analyst for Microsoft
- **Session 2**: Using Ratio-based Performance Analysis in Performance Analyst for Microsoft
- **Session 3**: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Microsoft
- **Session 4**: Using Workload Performance Analysis in Performance Analyst for Microsoft (DBArtisan)
- **Session 5**: Using SQL Performance Analysis in Performance Analyst for Microsoft
- **Session 6**: Using Operating System Performance Analysis in Performance Analyst for Microsoft
- **Session 7**: Identifying and Getting Help With Performance Problems Using Performance Analyst for Microsoft
- **Session 8**: Fixing Identified Problems Using Performance Analyst for Microsoft

You can use this basic tutorial as a roadmap of product highlights.

After starting this tutorial, you can select Help from the menu to find many additional resources that complement and build on many of the activities shown in this brief guide.
Session 1: Getting Started with Performance Analyst for Microsoft

Download and Install

You can obtain the latest version of Performance Analyst by downloading the DBArtisan software from the Embarcadero Web site at http://www.embarcadero.com/downloads/downloaddbartisan.asp. Performance Analyst runs fully contained within DBArtisan so you will need the DBArtisan product to use Performance Analyst (although Performance Analyst can also run in standalone fashion within a Microsoft Internet Explorer Web browser).

Click Download, and follow the steps indicated. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for 14 days. After that time, a permanent license is needed.

Overview of Performance Analyst for Microsoft

When DBArtisan is connected to a Microsoft SQL Server database, you can open Performance Analyst two ways:

1. On Utilities menu, select Performance Analyst.

For Performance Analyst to work, several procedures need to be installed by the SA account. When Performance Analyst is first invoked, it will check for the presence of this package and if it has not been installed, the product will prompt you to install it. Once created, any account with access to these procedures may monitor databases using Performance Analyst. No other objects need to be installed on a monitored database.

Performance Analyst for Microsoft Product Navigation

Navigating through Performance Analyst is easily accomplished through two main mechanisms:

1. The main Performance Analyst toolbar contains buttons that invoke the major performance analysis views within the product as well as frequently used actions like Refresh and Performance Threshold Customizations.

2. Positioning the mouse pointer on any area within Performance Analyst and clicking the right mouse button will bring up a navigation menu that allows you to easily move between any of the main Performance Analyst home pages and drill down views. The right mouse menu also contains context sensitive options like drilling down further into a particular statistic, copying the display to a text file, and more.
Proceed to Session 2: Using Ratio-based Performance Analysis in Performance Analyst for Microsoft
Session 2: Using Ratio-based Performance Analysis in Performance Analyst for Microsoft

Ratio-based analysis has been around for many years, and used to be the only technique database administrators used when they were called on to diagnose the cause of a database slowdown. Performance ratios are very good roll-up mechanisms for busy DBAs, making possible the analysis-at-a-glance approach, however ratios must be computed correctly for them to be meaningful. Key ratios in Performance Analyst are calculated using delta statistics, which is superior to computing ratios with cumulative values. Delta statistics, which are values derived by using the before and after measures in each statistical refresh done in Performance Analyst, lets you see changes in performance metrics that would otherwise be invisible if cumulative statistics were used. Performance Analyst makes it easy to see the ratios that are computed with delta statistics vs. cumulative. A triangle symbol denotes a delta-based statistic, while square symbols represent a cumulative-based measure.

Ratio-based analysis is available for all performance categories (memory, etc.) where ratios can assist in determining the performance level of a database. For example, if you would like to see memory-specific ratios, on the Performance Analyst toolbar click Memory. Performance Analyst displays the Memory home page that showcases all important memory-related ratios.

Obtaining Detail Information for a Ratio using Performance Analyst for Microsoft

A ratio gives you a global picture for a particular performance measure. However, you often need more information regarding a statistical measure so you can make an informed decision. Performance Analyst has easy-to-use drill down features that make obtaining detailed information for various ratios a breeze.

For example, to view more information for the Buffer Cache Hit Ratio statistic, do the following:

1. On either the Main Home page or the Memory Home page, locate the Buffer Cache Hit Ratio statistic.

2. Position the pointer over the statistic.

The pointer changes to a hand symbol.

3. Double-click the left mouse button.

Performance Analyst opens the Buffer Cache tab of the memory drill down view.

OR

Right-click the statistic, select Details.
OR

Select Navigate to, Memory, Buffer Cache.
Performance Analyst opens the **Buffer Cache** tab of the memory drill down view.

Proceed to [Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Microsoft](#)
Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Microsoft

When a Microsoft SQL Server database is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things, or it can be an indicator that a database bottleneck exists. Bottleneck analysis is a valid method of measuring performance because it helps you track where a database and user sessions have been spending their time. If latch contention or heavy table-scan activity has been dragging a database’s performance down, you can use bottleneck analysis to confirm the actual root cause.

Performance Analyst uses two broad areas of metrics to form its bottleneck analysis. The first is the Microsoft SQL Server wait event interface, which displays where the database and user sessions have been bottlenecked. But, when using bottleneck analysis you can not rely only on the information contained in the wait event views that Microsoft SQL Server provides. For example, an object may attempt to extend into another extent of space in a tablespace and yet, be denied if no such free space exists. Such a failure will not be reflected in any wait event, but still represents a very real bottleneck to the database. For this reason, Performance Analyst also shows non-wait event based bottlenecks that represent a very real threat to a database’s availability and performance.

Performance Analyst prominently displays bottleneck analysis on every performance home page. The Main home page, displays a summary of all key bottlenecks threatening the database. You can also see specific bottlenecks for memory, I/O, space, objects, and users by navigating to each home page and viewing the Bottleneck Analysis section for that home page. For example, to see bottlenecks that specifically relate to I/O, do the following:

1. On the toolbar, click the I/O button.
2. Locate the Bottleneck Analysis section at the lower-left portion of the screen.

The I/O bottleneck analysis section displays the Top I/O Wait Events by wait count and wait time, along with the Hottest Database and Log Files.

Obtaining Detail on System Bottlenecks Using Performance Analyst for Microsoft

You can easily obtain more information regarding global bottlenecks that are plaguing a database by drilling down into a particular bottleneck metric. For example, if you would like to see more data regarding the current top system bottlenecks, do the following:

1. Open the Main home page.
2. Double-click the Top System Bottlenecks area.
Performance Analyst opens the System Waits view.

3. Or right-click anywhere in Performance Analyst, point to Users, and then click System Waits.

Performance Analyst opens the System Waits view.

The System Waits view displays critical details regarding all the wait events that Microsoft SQL Server has recorded. You can easily see what events that occurred the most often as well as the events that have accumulated the most wait time.

**Tip:** If you would like to see an expanded view of the System waits grid shown on the top of the System Waits view, click the Expand button located at the top right corner of the section. All section views in Performance Analyst can be maximized/minimized using this control.

### Viewing Detail for Session Bottlenecks Using Performance Analyst for Microsoft

Not only can you obtain detail information for system bottlenecks, but you can also use Performance Analyst to get drill down information regarding session-level bottlenecks. There are several layers to session-level details you can view.

To see more information regarding session-level waits, do the following:

1. Open the Main home page.
2. Double-click the Top Session Bottlenecks area.

**OR**

3. Right-click anywhere in Performance Analyst, point to Users, and then click Session Waits.

Performance Analyst opens the Session Waits drill down view.

When you are in the Session Waits drill down view, to drill further into a session’s details, do the following:

1. In the Historical Waits or Current Waits grid, select a session that appears to be experiencing critical waits.
2. Double-click the session or right-click, and then select Details.

Performance Analyst opens a drill down view that shows key statistics for the selected session, including its current work activities, wait events, and SQL statements.

Proceed to [Session 4: Using Workload Performance Analysis in Performance Analyst for Microsoft (DBArtisan)]
Session 4: Using Workload Performance Analysis in Performance Analyst for Microsoft

Key ratios give you a global perspective on database activity. Bottleneck analysis gives you insight into things that are holding up user activity and throughput. But another technique is necessary if a database professional is to really get a handle on what’s occurring inside a badly performing database.

Workload analysis involves the investigation of two critical areas of a database’s performance:
  - Session resource consumption and activity
  - SQL execution

Without looking at these two key performance categories, you can miss a lot of what could be responsible for perceived performance problems. When performance on a database takes a sudden nosedive, it is not uncommon to find one or two sessions that are causing the bulk of the workload. Finding these processes can be easily accomplished by viewing session metadata coupled with resource consumption and statistical execution statistics.

Pinpointing Top Resource Consumers Using Performance Analyst for Microsoft

Performance Analyst identifies top resource consumers in a couple of different ways. On the main home page, Performance Analyst highlights the top resource sessions across I/O, memory usage, and CPU consumption. The percentage used across all statistical categories are displayed so a DBA can immediately pinpoint a session that is using all or most of a particular resource. The top resource sessions are also displayed on the memory, I/O, and other home pages as well with a listing for the top sessions for that category (for example, the top memory users appear on the memory home page, etc.)

Getting Workload Details Using Performance Analyst for Microsoft

Performance Analyst offers several details on top resource sessions in addition to the summaries provided on each home page. A detailed and flexible top sessions view lets you view a summary of all the major resource sessions on the database as well as every critical detail regarding each session connected to the database.
Further drill downs are available that highlights specific details regarding each session’s activities and submitted SQL. To see detailed information regarding a session identified in one of Performance Analyst’s Workload Analysis sections, do the following:

1. In a Workload Analysis display, position the pointer over one of the processes.
2. Double-click the process or right-click, and then select Details.

If you want like to see all key workload analysis metadata for sessions, do the following:

1. On the toolbar, click the Top Sessions button.

OR

2. Right-click anywhere in Performance Analyst, point to Users, and then click Session Waits.

Proceed to Session 5: Using SQL Performance Analysis in Performance Analyst for Microsoft
Session 5: Using SQL Performance Analysis in Performance Analyst for Microsoft

SQL-based performance analysis is really a subset of Workload Analysis. Understanding current and historical SQL execution patterns lets you to have the second set of data points necessary to properly perform workload analysis.

Uncovering Resource-intensive SQL Using Performance Analyst for Microsoft

Performance Analyst offers plenty of insight into SQL performance and execution patterns. Each one of the home pages depicts the most costly SQL statements as determined by a variety of different metrics for that performance category (most physical, logical I/O, etc.) For example, Performance Analyst might show that a single SQL statement is responsible for almost 60 percent of all the CPU consumption on the database.

Getting Details on Top SQL with Performance Analyst for Microsoft

Getting details on identified SQL statements is easy in Performance Analyst. For example, if you would like to see further information on a SQL statement identified on the Performance Analyst Home page, do the following:

1. In the SQL Analysis section, position the pointer over Hash Values.
2. Double-click or right-click, and then select Details.

Performance Analyst opens the Top SQL summary page that shows a breakdown of all top SQL statements along with their execution statistics.

If you would like to see the full SQL text of a SQL statement, do the following

1. In the Top SQL Details section, double-click a statement.

Performance Analyst opens the SQL Details tab of the Top SQL view to display the entire SQL statement and the execution metrics. While on this pane, you can also perform an EXPLAIN of the SQL statement and examine its access path information.

To automatically tune a problem SQL statement if you have Embarcadero SQL Tuner installed on your workstation, do the following:

1. On the SQL Details tab, select a problem statement, and then click the Tune SQL button.

SQL Tuner opens and you can begin a tuning session.
Session 6: Using Operating System Performance Analysis in Performance Analyst for Microsoft

In many scenarios, an optimally tuned database may not perform well because there are constraints imposed by the system where the database is running. These constraints may include processes competing with the database server for resources (CPU, I/O or Memory), a slow CPU, insufficient I/O devices, and insufficient memory. Performance Analyst allows the DBA to examine the relevant operating system metrics for Windows Platforms (NT /2000/XP/2003) as they relate to SQL Server.

To view the operating system metrics of the machine hosting the SQL Server you are monitoring, do the following:

1. Click the OS Performance Analyst toolbar button.

OR

2. Navigate to the OS Home Page by going to OS, and then Home.

Note: The first time you invoke the OS feature you will be prompted for an operating system login. Please specify the correct operating system, host name, username & password and protocol.

The Operating System home page has been designed in a similar fashion as the datasource home page. On this page you can see the pertinent operating system metrics displayed in five quadrants broken down into the following categories:

- Resource Usage
- Memory Analysis
- Disk Analysis
- Workload Analysis
- Bottleneck Analysis

Obtaining Details on the Operating System Using Performance Analyst for Microsoft

You can easily obtain more information regarding operating system problems that are degrading database performance by drilling down into a particular analysis quadrant. For example if you’d like to see more information regarding the processes running on the host machine, do the following:

1. Navigate to the Performance Analyst Operating System home page.

2. Double-click the Top Memory Processes in the Workload Analysis quadrant.
Performance Analyst opens the Processes Drilldown view.

OR

3. Right-click anywhere in Performance Analyst and select the Navigate to, OS, and then Processes.

The Processes detail tab shows all the processes on the host machine. From this view you can easily determine which processes are showing high marks in I/O or CPU, for example, by simply double clicking on the column headers and sorting the processes in ascending or descending order.

Proceed to Session 7: Identifying and Getting Help With Performance Problems Using Performance Analyst for Microsoft
Session 7: Identifying and Getting Help With Performance Problems Using Performance Analyst for Microsoft

You do not have to be an advanced expert in performance tuning to spot trouble in a database if you use Performance Analyst. There are a number of mechanisms in the tool that help you quickly locate areas of concern within a database.

Using the Alarm Log in Performance Analyst for Microsoft

Performance Analyst has a central and flexible alarm log that lists every performance violation found in all monitored databases. Unlike some products that only show you alarms for a particular database, Performance Analyst lists all alarms for each database you are monitoring in one central log so you can see every problem in one place. To view the Performance Analyst Alarm log, do the following:

1. On the toolbar, click the Alarms button.

Once in the Alarm log, you can perform a number of actions including:

- Selecting an alarm and viewing the application page that shows details regarding the metric in violation.
- Filtering the types of alarms shown through the Options dialog.
- Clearing all current alarms.
- Copying or saving the Alarm log into a different format.

To select any of these options, do the following:

1. Position the pointer over any area of the Alarm Log.
2. Right-click and In the shortcut menu, select an option.

Recognizing Performance Violations Using Performance Analyst for Microsoft

Performance Analyst makes it easy to visually pinpoint performance violations in a database. Any statistic that does not conform to your predefined performance standards is colorized in any view that it appears so you can easily see potential troublespots.

The colors used to highlight a particular performance violation depend on the severity of the problem. Performance Analyst uses several layers of performance standards/threshold violations with each layer being represented by a different color. You can control everything regarding threshold violations, including how thresholds are
determined, their color representation in Performance Analyst’s display, and more by using the Threshold Template feature of Performance Analyst.

How can Performance Analyst inform you of performance violations in your database if you minimize the product to your desktop and are working on other things? Even if Performance Analyst is not right in front of you, it can still let you know that a problem has been found in your database through the systray alarm icon. When Performance Analyst detects a problem in one of your databases, one of the things the product does is enable an alarm icon in your workstation’s systray area that communicates the presence of alarms in your database. So even if the Performance Analyst interface is not in sight, the product can let you know that something in your database requires attention.

**Creating Threshold Templates for Performance Analyst for Microsoft**

How does Performance Analyst know what to signal as a problem in a database? It uses predefined performance standards that you define and enforce. All of this is accomplished by using Performance Analyst’s Threshold templates. A template is a set of performance metrics and their thresholds that can be reused to enforce performance standards across any number of databases. Embarcadero provides a default performance template that contains nearly all of the most-watched performance statistics so you can begin monitoring with confidence right out of the box. However, you can create your own Threshold templates so you only are alerted to performance violations that are important to you and your particular environment.

To view or create Threshold templates, do the following:

1. On the toolbar, click the Thresholds button.

Performance Analyst opens the **Threshold Template Properties** dialog.

The **Threshold Template Properties** dialog lets you select the options to add or edit templates, as well as other maintenance options. For example, you can copy the original Embarcadero Threshold template and modify it to fit your own needs. You can control what statistics are sampled for performance violations as well as the levels of severity you would like reported. Once you are satisfied with your template, you can save it and then apply it to one or more datasources in one action to immediately begin enforcing your performance standards.

**Getting Help With Performance Problems Using Performance Analyst for Microsoft**

As databases become more complex, so do the problems that plague them. Knowing what to do for a particular performance problem can be hard in some cases, but Performance Analyst helps by providing a complete set of expert help that you can use as a guide when performance problems occur. To obtain expert help for any statistic shown in Performance Analyst, do the following:
1. Position the pointer over a statistic that you need help.

2. Right-click and select Help.

The Expert Help gives you a general description of the statistic, the range of values that are considered optimal, and some suggestions on how to fix a problem situation. Expert help can also be invoked for any of the Ratio, Bottleneck, SQL, or Workload Analysis sections shown on every home page by clicking on the help icon for that section, which is located at the top right corner of the section.

Proceed to Session 8: Fixing Identified Problems Using Performance Analyst for Microsoft
Session 8: Fixing Identified Problems Using Performance Analyst for Microsoft

Finding performance problems is one thing, but fixing them is another. Many performance monitors point out a particular problem in a database, but then offer no way to actually correct the situation. Such is not the case with Performance Analyst. Because of its tight integration with DBArtisan, certain problems found in Performance Analyst can be visually corrected by DBArtisan.

A Space Problem Correction Example

If an Microsoft SQL Server tablespace is about to run out of free space, Performance Analyst can issue an alarm that a space shortage exists. Once the space problem has been identified, do the following:

1. On the Space home page toolbar, click the Space button.
2. In the Space Analyst grid, right-click a tablespace, and then select Manage with DBArtisan.

DBArtisan opens an editor where you can perform corrective actions, such as enabling Autoextend for the tablespace, resizing the tablespace’s existing datafile(s), or adding a new datafile for the tablespace.
Microsoft SQL Server Performance Analyst Statistics

This section includes expert help for all Microsoft SQL Server statistics in the Embarcadero Performance Analyst views and pages:

- Home View (SQL Server Performance Analyst)
- Memory View (SQL Server Performance Analyst)
- I/O View (SQL Server Performance Analyst)
- Space View (SQL Server Performance Analyst)
- Users View (SQL Server Performance Analyst)
- Database View (SQL Server Performance Analyst)
- OS View (SQL Server Performance Analyst)
- Top SQL View (SQL Server Performance Analyst)
Home View (SQL Server Performance Analyst)

The Embarcadero Performance Analyst Home page lets you review availability and overall performance of all monitored databases from a single window. Statistics on the Home view are organized into the following categories:

- **Key Ratio Analysis Pane**
- **Bottleneck Analysis Pane**
- **SQL Analysis Pane**
- **Storage Analysis Pane**
- **Workload Analysis Pane**

**Key Ratio Analysis Pane**

Database performance analysts typically use one of two methods for examining the performance levels of a database - ratio-based or wait/bottleneck-based. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for busy DBA's to use for at-a-glance performance analysis. Many DBAs have large database farms to contend with and cannot spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving DBAs a few solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are certainly many opinions as to what rules to follow, there are some standards that should always be adhered to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that a DBA will examine come from the master.sysperfinfo performance table. This table maintains a count of various statistics for the server and particular databases since the server was brought up. For servers that are kept up for long periods of time, these values can grow quite large and will impact how a particular ratio that a DBA might be looking at is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each SQL Server's individual 'personality' with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.
The following ratios are used on the Performance Analyst Home page to succinctly communicate the general overall performance levels of the monitored database. The statistics available in this pane, are duplicates of statistics available on the Key Ratio Analysis Pane of the Home View (DBArtisan - SQL Server Performance Analyst) page:

**Buffer Cache Hit Ratio**

Data read from memory will produce end-user response times many times faster than when that same data is read from disk. Keeping physical I/Os to an absolute minimum is one of the purposes of the SQL Server buffer/data cache.

The buffer cache hit ratio is a terrific indicator of how often user requests for data are satisfied through memory vs. being physically read from disk.

**Location**

**Metrics**

To help ensure excellent performance, you want to keep your cache hit ratio in the neighborhood of 90% or higher. However, you should be aware that every server has its own 'personality' and might exhibit excellent performance with below average readings for the cache hit ratio. You should also be aware that excessive logical I/O activity can produce a very high cache hit ratio while actually degrading overall database performance. Consistently viewed low readings (60% or lower) might require tuning attention on the part of the DBA.

**Correction**

Ensure SQL Server is configured to use as much physical memory as possible by checking the Max Server memory configuration option. Also, consider increasing your SQL Server Min. Memory parameter to allocate more memory to SQL Server. (Note that to obtain optimal values for these parameters, an option is to install more physical RAM to your server.) Check for any large objects that are pinned in memory that could possibly be removed. Often a user process is taking a large amount of memory due to an inordinate amount of I/O.

**Procedure Plan Hit Ratio**

The SQL Server procedure cache is used to hold the execution plans for all Transact-SQL statements currently executing in the server. When a user executes a Transact-SQL statement, SQL Server looks in the procedure cache for a query plan to use.

This statistic is the percentage of query plan requests generated by stored procedures that are found in the procedure cache area. The percentage of times that a statement's plan and definition can be referenced in memory, the better the procedure execution time.
A high procedure cache hit rate is a desirable thing. You should strive for a hit ratio between 95-100%, with 95% being a good performance benchmark for code reference. Note that when a database is first started, the procedure cache hit rate will not be at an optimal level because all code being used will be relatively new, and as such, must be read in from disk and placed into the cache. If, however, after a solid hour or two of steady database time, the procedure cache hit rate has not increased to desirable levels, you should look into the possibility of increasing the amount of memory allocated to the cache.

First, ensure SQL Server is configured to use as much physical memory as possible by checking the Max Server Memory configuration option. Also, consider increasing your SQL Server Min Memory parameter to allocate more memory to SQL Server. (Note that to obtain optimal values for these parameters, an option is to install more physical RAM to your server.) Check for any large objects that are pinned in memory that could possibly be removed.

Ad Hoc SQL Hit Ratio

When an ad hoc SQL statement is issued, the query plan is then stored in the SQL Server procedure cache area. If the identical ad hoc statement is launched in the future, SQL Server uses the query plan already stored in the procedure cache if it is still there. The Ad Hoc SQL Hit Ratio statistic defines the percentage of times that a query plan for an ad hoc SQL statement is found in the procedure cache.
A high ad hoc hit rate is desirable, but is harder to maintain at a high level than something like a procedure cache hit rate. Therefore, an 80% or greater ad hoc cache hit rate is a good performance benchmark for code reference. Note that when a database is first started, the ad hoc cache hit rate will not be at an optimal level because all code being used will be relatively new, and as such, must be read in from disk and placed into the cache. If, however, after a solid hour or two of steady database time, the ad hoc cache hit rate has not increased to desirable levels, you should look into the possibility of increasing the amount of memory allocated to the cache.

Correction
First, ensure SQL Server is configured to use as much physical memory as possible by checking the Max Server Memory configuration option. Also, consider increasing your SQL Server Min Memory parameter to allocate more memory to SQL Server. (To obtain optimal values for these parameters, an option is to install more physical RAM to your server.) Check for any large objects that are pinned in memory that could possibly be removed.

Log Cache Hit Ratio
The Log Cache Hit Ratio represents the percentage of log cache reads satisfied from the log cache.

Correction
A low percentage on this statistic is not necessarily a bad sign, as it is possible that the information needed from the log will not be readily available in memory.

CPU Busy
The CPU Busy statistic represents the percentage of time that the CPU has spent working since the last refresh.
I/O Busy

The I/O Busy statistic represents the percentage of time that SQL Server has spent performing input and output operations since the last refresh.

Server Idle

The Server Idle statistic represents the percentage of time that SQL Server has spent idle since the last refresh.

Bottleneck Analysis Pane

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. And this is where wait-based or bottleneck analysis comes into play. DBAs use this form of performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps a DBA track where a database has been spending its time. If lock contention or heavy table scan activity has been dragging down database performance, a DBA can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, the DBA can drill down and oftentimes discover a fair amount of detail about which sessions and objects are causing the problem. The Performance Analyst Home page identifies the top system and session waits that might be currently a cause of lessened performance.

When using bottleneck analysis, you cannot rely only on the information contained in the wait events that SQL Server provides. For example, a database might be suspect or offline. Such a failure will not be reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that a DBA cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain...
an accurate performance risk assessment. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system. The Performance Analyst Home page displays space-related bottlenecks as well as other sources of contention/bottlenecks that might be dragging down the overall performance of your system.

The following bottleneck indicators are used on the Performance Analyst Home page to succinctly communicate the general overall performance level of the monitored database:

- **Current Object Blocks**
- **DB’s Low on Space**
- **Deadlocks**
- **Errors in Current Log**
- **Logs Low on Space**
- **Offline Databases**
- **Suspect Databases**
- **Table Lock Escalations**
- **Top System Bottlenecks**

### Top System Bottlenecks

The Top System Bottlenecks display identifies the top waits that have occurred on SQL Server based on the wait time.

**Location**  
Microsoft SQL Server Performance Analyst Statistics > Home View (DBArtisan - SQL Server Performance Analyst) > Bottleneck Analysis Pane

**Correction** Wait events can be hard to interpret at times. If you see a particular event that has caused a lot of wait time, you can review the information in this link (Microsoft Knowledge Base Article - 244455) to help understand the cause and potential remedy:  
http://support.microsoft.com/default.aspx?scid=kb:en-us;Q244455

### Current Object Blocks

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Blocks are most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency. Unless a process times out via an application timeout mechanism, or the process has specified a timeout period via the SET LOCK_TIMEOUT command, a process waiting for a lock will wait indefinitely.
You should immediately investigate any indicator above zero, before the situation has a chance to mushroom.

Correction Once discovered, a blocking lock situation can normally be quickly remedied - the DBA issues a KILL against the offending process, which eliminates the user’s stranglehold on the objects they were accessing. Then other user processes, almost always, complete in an instant. Discovering the blocked lock situation is made easier by using tools like Performance Analyst, but preventing the blocking lock situation in the first place is where it gets tricky. The DBA can drill down into Users View (SQL Server Performance Analyst) detail and see all current blocking locks, learning exactly which sessions are holding the currently restrictive locks. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. By default, all processes wait indefinitely for locks in SQL Server. You can change this behavior by using the SET LOCK_TIMEOUT command, which limits the number of seconds that a process will wait for a lock before timing out.

**Deadlocks**

This metric shows the number of deadlocks per second detected by SQL Server. Deadlocks occur when processes cannot proceed because they are waiting on a set of resources held by each other or held by other processes.
Metrics  Consistently seeing deadlock counts greater than zero will indicate that some user processes are experiencing delays in completing their work. When SQL Server identifies a deadlock, it resolves the situation by choosing the process that can break the deadlock. This process is termed the deadlock victim. SQL Server rolls back the deadlock victim's transaction, and then notifies the process' application by returning an error message. It also cancels the process’ request and allows the transactions of the remaining processes to continue. SQL Server always attempts to choose the least expensive thread running the transaction as the deadlock victim.

Correction  Because SQL Server automatically resolves deadlock situations, you should proactively work to prevent them in the first place. The culprit of most blocking lock and deadlock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. You can change default deadlock behavior by using the SET DEADLOCK_PRIORITY command, which reprioritizes a process’ position in a deadlock situation.

Table Lock Escalations

The Table Lock Escalations statistic represents the number of times locks on a table were escalated.

Metrics  Many table lock escalations could indicate contention problems. If increasing numbers of table lock escalations are viewed at the same time as blocking or deadlock problems, then the application design might be at fault.

Suspect Databases

The Suspect Databases statistic represents the number of databases SQL Server has marked as suspect. Databases are marked suspect by SQL Server if they fail during automatic recovery, which is performed at server startup. If serious damage is experienced by a database during regular uptime, SQL server will also mark a database suspect.
You should not have any suspect databases found on any production server. You should immediately investigate any non-zero numbers for this statistic.

The steps to handling a suspect database will vary from one installation to another. However, there are some general guidelines you can use to troubleshoot a suspect database. Begin by examining the SQL Server error log for clues as to what caused the database to be marked as suspect. It is not unusual for a server to run out of physical disk space on drives used by SQL Server. When this happens, recovery for databases can sometimes fail with the end result being SQL Server marking a database as suspect. To remedy this situation, you should free up space on the identified drives or add files to the newly marked suspect database. This can be accomplished by utilizing the two procedures - `sp_add_data_file_recover_suspect_db` and `sp_add_log_file_recover_suspect_db` stored. For version 7.0 of SQL Server, you must use the `sp_resetstatus` stored procedure to reset the suspect status flag for the database in question, use the alter database command to add new datafiles to the database, and then stop/start the SQL Server. Many times, suspect databases are caused by SQL Server not being able to access a database or log file. This happens if a particular physical hard drive has become unavailable, but also can occur if another operating system process has obtained exclusive access to a file. If this scenario proves to be true, once you have ensured that the file(s) are available once again to the operating system, you can use the `sp_resetstatus` stored procedure to reset the suspect status flag for the database and then stop/start the SQL Server. If none of these solutions are possible, you will likely have to restore your database using the last full and transaction log backups.

Errors in Current Log

SQL Server records various system events in its system or error log. The majority of messages placed into the log are informational in nature, however since some contain
critical messages, you should immediately review them. Performance Analyst indicates the number of actual error messages in the most recent error log so you know if there are potential events that require your attention.

**Location** Microsoft SQL Server Performance Analyst Statistics > Home View (DBArtisan - SQL Server Performance Analyst) > Bottleneck Analysis Pane

**Correction** Drill down into the Error Log Tab within Performance Analyst to view the actual error messages.

### DB’s Low on Space

A SQL server contains many databases, some of which are devoted to system-level activities (the master and tempdb databases, for example) and others that hold user data. The Databases Low on Space statistic indicates databases that have fallen below a recommended percentage of free space.

**Location** Microsoft SQL Server Performance Analyst Statistics > Home View (DBArtisan - SQL Server Performance Analyst) > Bottleneck Analysis Pane

**Metrics** This might or might not be a problem. Some databases are not dynamic in nature (meaning they are not expected to grow in size) and are sized so very little free space is present. However, growing databases are another situation and might require DBA intervention if their free space amounts run low.

**Correction** If the percent used amount of a database is approaching problematic levels, there are three ways a DBA can rectify the situation: The DBA can resize the current file(s) used by the database via an ALTER DATABASE … MODIFY FILE command. The DBA can add a new file to the database via the ALTER DATABASE … ADD FILE command. The DBA can modify the file(s) used by the database to automatically grow by using the ALTER DATABASE … MODIFY FILE … FILEGROWTH command. You should also ensure that the MAXSIZE setting for each file is set appropriately. You should also ensure that enough physical space exists on the server to accommodate additional database space.

### Logs Low on Space

Each database in SQL Server has a transaction log, which is a serial record of all modifications that have occurred in a database as well as the transactions that caused each change. The Logs Low on Space statistic indicates transaction logs that have fallen below a recommended percentage of free space.
Metrics

If any log’s used space exceeds the Performance Analyst recommended thresholds, then the DBA should take action to ensure that the log does not run out of available free space.

Correction

There are several things a DBA can do to ensure that a database’s log does not run out of available free space: First, most transactional-oriented databases should have their logs assigned to a separate physical drive than the database. This prevents competition for space between the log and the database itself, allows the log to be monitored for space more effectively, and improves performance. If the database is not critical in nature, you can set the truncate log on checkpoint option trunc log on chkpt, which will eliminate any non-active space in the log when a database checkpoint occurs. Critical databases needing higher levels of recovery should have schedules established that regular perform transaction log dumps. Doing so ensures better recovery scenarios as well as a reduced risk of the transaction log running out of space. If a critical transaction log becomes full, it might be impossible to use standard procedures to dump transactions and reclaim space. The dump operation will likely have to incorporate the no log or truncate only options. If a transaction log continuously approaches dangerously low levels of free space, then the DBA should allow the underlying file(s) of the log to automatically grow to meet the demand. This can be accomplished by using the ALTER DATABASE … MODIFY FILE … FILEGROWTH command. You should also ensure that the MAXSIZE setting for each file is set appropriately. The DBA should also be on the lookout for large load or data modification operations that do not make use of prudently timed commit points. A single, large transaction has the ability to overwhelm any transaction log since only non-active space in the transaction log is removed from log dumps or truncation operations.

SQL Analysis Pane

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured server down in terms of end-user response times.

Before you can identify problem SQL in your database, you have to ask the question - “What is bad SQL?” What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every SQL Server professional’s satisfaction. The table below lists some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:
### Criteria | Description
--- | ---
Reads | This is often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user’s request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at a statements’ logical I/O as well.

Writes | These can be caused by DML activity (INSERTs, etc.), but writes can also be indicative of heavy disk sort activity.

CPU | This is how much CPU time the query took to parse, execute, and fetch the data needed to satisfy the query.

Elapsed Time | This is how much time the query took to parse, execute, and fetch the data needed to satisfy the query. It should not include the network time needed to make the round trip from the requesting client workstation to the database server.

There are other criteria that you can examine like sort activity or access plan statistics (that show items like Cartesian joins and the like), but more often than not, these measures are reflected in the criteria listed above.

The SQL Analysis section provides you with a quick overview of the percentage of Reads, Writes, CPU, and Elapsed Time the most expensive SQL statements tracked by Performance Analyst have used. Depending on the page you are on, you might just see information regarding physical I/O activity or DML statements. For example, you might see that a SQL statement has caused 60% of all physical reads on the system, or that a procedure is responsible for 90% of all the CPU usage. To get information regarding the actual SQL text or stored procedure calls, drill down into the Top SQL details views.

**Note:** SQL Profiling is turned on by default in Performance Analyst so you can automatically collect SQL traffic. If you do not want to collect SQL execution information, use the options inside of Performance Analyst to disable SQL profiling.

### Metrics

When you begin to look for inefficient SQL in a database, there are two primary questions you should answer:

- What has been the worst SQL that has historically been run in my database?
- What is the worst SQL that is running right now in my database?

When Correction a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It might be that the query is in an inefficient Transaction SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.
There is the possibility that the SQL statement just is not tuned well. To determine that, you can drill down further into the Top SQL view and begin working with the query through EXPLAIN plan analysis and other techniques inside Embarcadero’s DBArtisan.

**Storage Analysis Pane**

While DBAs focus on memory settings and tuning SQL, they frequently forget how dangerous and insidious storage problems can be. This is not a good mindset because storage headaches can play a major role in wrecking an otherwise well-running database.

Storage problems generally take one of two forms:

- The ‘hit-the-wall’ variety that can bring things to a complete standstill.
- The ‘performance vampire’ kind that slowly drains the performance of a database over time.

Storage problems can bring the curtain down on a database very quickly, as in the case of a transaction log running out of free space. But storage problems can also silently work behind the scenes to slowly, but surely rob a database of its performance. For example, a hub table in a busy database might be accessed very quickly when an application is first given life, but over time, if it develops a heavy forwarded row problem, it can cause things to run very differently.

The Storage Analysis section of the Performance Analyst Home page displays the Total Used/Total Free Space of all tablespaces in the database. It also provides a count of the number of databases, files, and file groups that exist on the server. For more detailed information on database space, you can use the Performance Analyst Space View (SQL Server Performance Analyst) details.

**Total Used/Total Free Space**

These statistics represent the total used and free space available in all databases on the server. Although good to know, a more detailed listing by database is needed to determine where any actual space shortages exist on the server. This information can be viewed in the Performance Analyst Space View (SQL Server Performance Analyst) details.
If any one database or transaction log begins to approach the Performance Analyst recommended thresholds (and the objects contained within it are dynamic and growing as opposed to static), then the DBA should take action to prevent any future space allocation errors.

Here are a few things a DBA can do to prevent free space shortages: For Databases:
- The DBA can resize the current file(s) used by the database via an ALTER DATABASE ... MODIFY FILE command.
- The DBA can add a new file to the database via the ALTER DATABASE ... ADD FILE command.
- The DBA can modify the file(s) used by the database to automatically grow by using the ALTER DATABASE ... MODIFY FILE ... FILEGROWTH command.

You should also ensure that the MAXSIZE setting for each file is set appropriately.

For Transaction Logs:
- First, most transactional-oriented databases should have their logs assigned to a separate physical drive than the database itself. This prevents competition for space between the log and the database.
- Critical databases needing higher levels of recovery should have schedules established that regularly perform transaction log dumps. Doing so ensures better recovery scenarios as well as a reduced risk of the transaction log running out of space.
- Critical databases should establish a consistent log truncation schedule.
- If a critical transaction log becomes full, it might be impossible to use standard procedures to dump transactions and reclaim space. The dump operation will likely have to incorporate the no log or truncate only options.

If a transaction log continuously approaches dangerously low levels of free space, then the DBA should allow the underlying file(s) of the log to automatically grow to meet the demand. This can be accomplished by using the ALTER DATABASE ... MODIFY FILE ... FILEGROWTH command. You should also ensure that the MAXSIZE setting for each file is set appropriately.

You should also be on the lookout for large load or data modification operations that do not make use of prudently timed commit points. A single, large transaction has the ability to overwhelm any transaction log since only non-active space in the transaction log is removed from log dumps or truncation operations.

**Workload Analysis Pane**

When experiencing performance slowdowns, some of the first questions you should answer are:

- Who is currently connected to the database?
- What resources are they using?
- What are they currently executing?

The Workload Analysis section of the Performance Analyst Home page provides insight into the leading resource hogs of a server, as well as a count of total active and inactive processes. The Users View (SQL Server Performance Analyst) page lets you easily get detailed information into what each leading session is currently doing.
Workload Analysis statistics include:

- Active User Processes
- Inactive User Processes

**Metrics**

If any one session appears to be using more than 50% of a total resource (CPU, memory, etc.), then you should drill down into the session to find out what they are currently executing.

**Active User Processes**

The Active User Processes statistic represents the total number of active and open threads reported on the server. This number displays the number of processes actively performing work.

Location Microsoft SQL Server Performance Analyst Statistics > Home View (DBArtisan - SQL Server Performance Analyst) > Workload Analysis Pane

**Inactive User Processes**

This metric represents the total number of threads logged on to the server that are idle at the current time.

**Note:** This statistic is also available on the Home page under Users View (SQL Server Performance Analyst).

Location Microsoft SQL Server Performance Analyst Statistics > Home View (DBArtisan - SQL Server Performance Analyst) > Workload Analysis Pane

**Metrics**

A large number of inactive users could indicate user sessions that have mistakenly been left logged on. Since each user thread consumes a portion of memory on the server, to reduce resource usage, you should sever any sessions not needing a connection.

**Correction**

Drill down into the Session Waits Tab and check sessions that have many seconds idle and/or that have been logged on for very long periods of time, as indicated by the logon time column. After verifying that a session is no longer necessary, you can KILL it.
Memory View (SQL Server Performance Analyst)

In addition to a Home page, the Memory category of SQL Server Performance Analyst includes the following tabbed pages:

- Buffer Cache Tab
- Log Cache Tab
- Procedure Cache Tab

Home

The Home page of the Memory category includes the following sections and statistics:

- Key Ratio Analysis Pane
- Bottleneck Analysis Pane
- SQL Analysis Pane
- Memory Analysis Pane
- Workload Analysis Pane

Key Ratio Analysis Pane

Database performance analysts typically use one of two methods for examining the performance levels of a database - ratio-based or wait/bottleneck-based. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for busy DBA's to use for at-a-glance performance analysis. Many DBAs have large database farms to contend with and cannot spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving DBAs a few solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are certainly many opinions as to what rules to follow, there are some standards that should always be adhered to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that a DBA will examine come from the master.sysperfinfo performance table. This table maintains a count of various statistics for the server and particular databases since the server was brought up. For servers that are kept up for long periods of time, these values can grow quite large and will impact how a particular ratio that a DBA might be looking at is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of
each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each SQL Server's individual 'personality' with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following memory ratios are used on the Performance Analyst Home page to succinctly communicate the general overall memory performance levels of the monitored database:

- **Cache Used**
- **Procedure Cache Used**
- **Used Cache %**
- **Used Procedure Cache %**

The following statistics, available in this pane, are duplicates of statistics available on the Key Ratio Analysis Pane of the Home View (SQL Server Performance Analyst) page:

- **Buffer Cache Hit Ratio**
- **Procedure Plan Hit Ratio**
- **Ad Hoc SQL Hit Ratio**
- **Log Cache Hit Ratio**

**Cache Used**

The total MB of space that SQL Server is using in the buffer cache. Each instance of SQL Server has its own buffer cache where it stores recently used data pages to reduce physical I/O. The goal is to make the buffer cache large enough to maximize the ratio of logical reads to physical reads, but not so large that excessive memory swapping starts generating physical I/O to the pagefile.
Memory View (SQL Server Performance Analyst)

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Home > Key Ratio Analysis Pane

Metrics  A percentage consistently remaining close to 100% indicates a deficient amount of memory available to SQL Server.

Correction  First, ensure SQL Server is configured to use as much physical memory as possible by checking the Max Server Memory configuration option. Also, consider increasing your SQL Server Min Memory parameter to allocate more memory to SQL Server. (Note that to obtain optimal values for these parameters, an option is to install more physical RAM to your server.) Check for any large objects that are pinned in memory that could possibly be removed.

Procedure Cache Used

The total MB of space that SQL Server is using in its SQL/procedure cache. Microsoft has begun to transition from the term “procedure cache” to “SQL cache” to define this area of memory. The reason being that in SQL Server’s past, this area was devoted exclusively to holding query plans for stored procedures only.

The SQL Cache (procedure cache) is the part of the SQL Server memory pool that is used to store execution plans for Transact-SQL batches, stored procedures, and triggers. Execution plans record the steps that SQL Server must take to produce the results specified by the Transact-SQL statements contained in the batches, stored procedures, or triggers.

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Home > Key Ratio Analysis Pane

Used Cache %

The Used Buffer Cache Percent statistic represents the total percentage of memory that is in use in the SQL Server buffer cache. Each instance of SQL Server has its own buffer cache where it stores recently used data pages to reduce physical I/O. The goal is to make the buffer cache large enough to maximize the ratio of logical reads to physical reads, but not so large that excessive memory swapping starts generating physical I/O to the pagefile.
Memory View (SQL Server Performance Analyst)

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Home > Key Ratio Analysis Pane

Metrics  A percentage used consistently remaining close to 100% indicates a deficient amount of memory available to SQL Server.

Correction  First, ensure SQL Server is configured to use as much physical memory as possible by checking the Max Server Memory configuration option. Also, consider increasing your SQL Server Min Memory parameter to allocate more memory to SQL Server. (Note that to obtain optimal values for these parameters, an option is to install more physical RAM to your server.) Check for any large objects that are pinned in memory that could possibly be removed.

Used Procedure Cache %

The total percentage of memory that SQL Server is using in its SQL/procedure cache. Microsoft has begun to transition from the term “procedure cache” to “SQL cache” to define this area of memory. The reason being that in SQL Server’s past, this area was devoted exclusively to holding query plans for stored procedures only.

The SQL Cache is the part of the SQL Server memory pool that is used to store execution plans for Transact-SQL batches, stored procedures, and triggers. Execution plans record the steps that SQL Server must take to produce the results specified by the Transact-SQL statements contained in the batches, stored procedures, or triggers.

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Home > Key Ratio Analysis Pane

Bottleneck Analysis Pane

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. And this is where wait-based or bottleneck analysis comes into play. DBAs use this form of performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps a DBA track where a database has been spending its time. If lock contention or heavy table scan activity has been dragging down database performance, a DBA can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, the DBA can drill down and oftentimes discover a fair amount of detail about which sessions and objects are causing the problem.

Memory bottlenecks can cause performance degradation in an otherwise well-running database. Typically, these bottlenecks center around the SQL Server latches, which are lightweight locks used to protect certain resources in memory. To help you identify such problems, the following statistics are presented on the Performance Analyst Memory home page:
Latch Waits/Sec

This metric represents the number of latches per second that could not be satisfied immediately by SQL Server. Latches are lightweight, mini-locks that are used to protect actions and resources used inside transactions.

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Unless accompanied by long wait times, latch waits should not pose too much of a performance problem in normal SQL Server installations. If you have a high number of latch waits per second, then it is likely that SQL Server is also sporting a low buffer cache hit ratio and is being forced to perform extra physical I/O.

Total Latch Wait Time

Latches are lightweight, mini-locks that are used to protect actions and resources used inside transactions. The total latch wait time statistic represents the sum total of all latch wait time that has occurred on the system.

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Unless accompanied by long wait times, latch waits should not pose too much of a performance problem in normal SQL Server installations. If you have a high number of latch waits per second, then it is likely that SQL Server is also sporting a low buffer cache hit ratio and is being forced to perform extra physical I/O.

Top Latch Waits

The Top Latch Waits graph depicts the top latch waits by wait time.
Location: Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics: Latch waits rarely impact performance, however seeing latch waits with high wait time might indicate an area that needs further investigation.

Correction: Wait events can be hard to interpret. If you see a particular event that has caused a lot of wait time, you can review the information in this Microsoft Knowledge Base Article to help understand the cause and potential remedy: http://support.microsoft.com/default.aspx?scid=kb;en-us;Q244455

SQL Analysis Pane

When SQL Server executes a set of SQL (ad hoc, procedure, trigger, etc.), it places the code into its procedure cache. The SQL Analysis section of the Performance Analyst Memory page provides a summary of the total memory pages currently in use by the various SQL types (procedure, ad hoc, etc.)

The SQL Analysis section provides you with a quick overview of the percentage of Reads, Writes, CPU, and Elapsed Time the most expensive SQL statements tracked by Performance Analyst have used. Depending on the page you are on, you might just see information regarding physical I/O activity or DML statements. For example, you might see that a SQL statement has caused 60% of all physical reads on the system, or that a procedure is responsible for 90% of all the CPU usage. To get information regarding the actual SQL text or stored procedure calls, drill down into the Top SQL details views.

Note: SQL Profiling is turned on by default in Performance Analyst so you can automatically collect SQL traffic. If you do not want to collect SQL execution information, use the options inside of Performance Analyst to disable SQL profiling.

Memory Analysis Pane

SQL Server uses various memory regions to accomplish various tasks (like retain frequently used data, procedures, etc.) and improve overall performance. At start up, SQL Server is allocated memory that will fall between the range of two configurable parameters: Min Memory and Max Memory. These statistics show you the amount of SQL Server memory allocated at present. In a normal SQL Server system, this number fluctuates as SQL Server uses more memory and releases unused memory back to the operating system. SQL Server also works in conjunction with the Windows Memory Manager, deallocating space when it detects that the operating system is unable to satisfy memory requests of other operating system processes. Depending on the version of SQL Server you are using, expect to deal with different memory regions. The table below describes some of the SQL Server memory regions:
Memory Scan | Description
--- | ---
Buffer Cache | The buffer cache is a memory pool of buffer pages into which SQL Server reads data pages for quick access.
Procedure Cache | Beginning with SQL Server version 7.0, you can place other SQL-related code objects in memory for reuse. Once SQL Server parses through and places a set of SQL of program code in memory, response time can be increased for subsequent calls to the same set of SQL or SQL code objects.
Connection Memory | The total amount of dynamic memory the server is using for maintaining connections.
Granted Workspace Memory | The total amount of memory granted to executing processes such as sort, hash, bulk copy operations, and so forth.
Lock Memory | The total amount of dynamic memory the server is using for locks.
Optimizer Memory | The total amount of dynamic memory the server is using for query optimization.
SQL Cache Memory | The total amount of memory used to retrieve stored SQL caches.

Workload Analysis Pane

It is not uncommon for one or two users to cause the majority of runtime problems that plague a server. The problem could be a runaway process, an untuned batch procedure, or other user-initiated operation.

If your database server does not have an overabundance of memory, then you should periodically check to see who your heavy memory users are along with the total percentage of memory each takes up. If you see one or two users who have more than 25-50% of the total memory usage, then you should further investigate the sessions to see what activities they are performing.

Buffer Cache Tab

The Buffer Cache Hit Ratio tab includes the following sections:

- **Top Twenty Buffer Cache Objects**
- **Total vs. Target Memory**
- **Cached Pages By Database**
- **Page Life Expectancy**

The following statistic, available on this page, duplicates a statistic on the Key Ratio Analysis Pane of the Home View (SQL Server Performance Analyst) page:
Top Twenty Buffer Cache Objects

SQL Server uses various memory regions to accomplish various tasks (like retain frequently used data, procedures, etc.) and improve overall performance. At start up, SQL Server is allocated memory that falls between the range of two configurable parameters: Min Memory and Max Memory. The Top Twenty Buffer Cache Objects chart shows you the amount of SQL Server memory allocated at present. In a normal SQL Server system, this number fluctuates as SQL Server uses more memory and releases unused memory back to the operating system. SQL Server also works in conjunction with the Windows Memory Manager, deallocating space when it detects that the operating system is unable to satisfy memory requests of other operating system processes. Depending on the version of SQL Server you are using, there are several memory regions you should expect to deal with. The table below describes the SQL Server memory regions:

<table>
<thead>
<tr>
<th>Memory Scan</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Buffer Cache</td>
<td>The buffer cache is a memory pool of buffer pages into which SQL Server reads data pages for quick access.</td>
</tr>
<tr>
<td>Procedure/SQL Cache</td>
<td>Beginning with SQL Server version 7.0, you can place other SQL-related code objects in memory for reuse. Once SQL Server parses through and places a set of SQL of program code in memory, response time can be increased for subsequent calls to the same set of SQL or SQL code objects.</td>
</tr>
<tr>
<td>Connection Memory</td>
<td>The total amount of dynamic memory the server is using for maintaining connections.</td>
</tr>
<tr>
<td>Lock Memory</td>
<td>The total amount of dynamic memory the server is using for locks.</td>
</tr>
<tr>
<td>Optimizer Memory</td>
<td>The total amount of dynamic memory the server is using for query optimization.</td>
</tr>
</tbody>
</table>

The Active and Free Page chart in Performance Analyst displays a count of active memory pages (those being used by SQL Server) and free pages (pages not being used).

Location: Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Buffer Cache Tab

Metrics: Seeing consistent high volumes of free pages might indicate that SQL Server is using more memory than necessary.

Total vs. Target Memory

Total memory is the amount of memory that’s currently in use by SQL server. Target memory is the amount of memory that could be used. SQL server dynamically adjusts its memory allocations depending either on workload up to the maximum memory.
configuration set by the DBA or the amount it thinks it should give other (non-SQL) server operations.

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Buffer Cache Tab

Metrics  When total memory approaches or reaches the maximum amount of target (defined) memory, then SQL server is experiencing memory pressure. You can try adding more RAM to the machine or adjusting memory ceiling limits imposed at the SQL server configuration level.

Cached Pages By Database

The Cached Pages By Database metric gives the amount of pages in memory devoted to database content compared to all other content.

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Buffer Cache Tab

Metrics  If you see that a large percentage of memory is devoted to database pages, the server is database page centric and not procedure plan centric. This can indicate that too many table scans are taking place, which might be flooding the buffer cache with infrequently used pages. You can determine if this is the case by looking at the page life expectancy metric. Page life expectancy readings of 300 seconds or less can indicate excessive table scan activity.

Page Life Expectancy

The page life expectancy metric indicates how long SQL server believes a page will stay in the buffer cache. Pages served from memory result in much shorter response times than pages read from disk into the cache. It’s best if frequently used data is pinned in the buffer cache.

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Buffer Cache Tab

Metrics  Readings of 300 seconds or less frequently mean that too many table scans are occurring and flooding the buffer cache with pages that are used rarely. Check the I/O access patterns on the I/O home page or the User I/O drill-down to confirm if this is the case.

Procedure Cache Tab

The Procedure Cache tab includes the following sections:

- Procedure Cache Hit Ratio
- Procedure/SQL Cache Detail
- Procedure/SQL Cache Summary
Procedure Cache Hit Ratio

The SQL Server procedure cache holds the execution plans for all Transact-SQL statements currently executing in the server. When a user executes a Transact-SQL statement, SQL Server looks in the procedure cache for a query plan to use.

The Procedure Cache Hit Ratio statistic is the percentage of query plan requests generated by stored procedures that are found in the procedure cache area. The greater the percentage of times that a statement’s plan and definition can be referenced in memory, the better the procedure execution time.

Location Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Procedure Cache Tab

Metrics A high procedure cache hit rate is a desirable thing. You should strive for a hit ratio between 95-100%, with 95% being a good performance benchmark for code reference. Note that when a database first starts, the procedure cache hit rate will not be at an optimal level because all code being used will be relatively new, and as such, must be read in from disk and placed into the cache. If, however, after a solid hour or two of steady database time, the procedure cache hit rate does not increase to desirable levels, you should look into the possibility of increasing the amount of memory allocated to the cache.

Correction First, ensure SQL Server is configured to use as much physical memory as possible by checking the max server memory configuration option. Also, consider increasing your SQL Server min memory parameter to allocate more memory to SQL Server. (Note that to obtain optimal values for these parameters, an option is to install more physical RAM to your server.) Check for any large objects that are pinned in memory that could possibly be removed.

Procedure/SQL Cache Summary

The SQL Server procedure/SQL cache holds often-referenced code object definitions and ad-hoc SQL. The Procedure/SQL Cache Summary lists each type of code object, the amount of memory each code type (trigger, ad-hoc SQL, etc.) consumes, and a total count of each type of code object.

Location Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Procedure Cache Tab

Metrics Seeing a lot of memory devoted to ad-hoc SQL plans might indicate an environment where sessions are submitting a lot of SQL requests. Many SQL Server DBAs like to control code submissions through stored procedures.

Procedure/SQL Cache Detail

Beginning with SQL Server version 7.0, other SQL-related code objects might be placed in memory for reuse. Once SQL Server parses through and places a set of SQL of program code in memory, response time can be increased for subsequent calls to the same set of SQL or SQL code object. The Procedure/SQL Cache Details section displays the top 1000 objects in the procedure/SQL cache. The table below describes the
information available in the Procedure/SQL Cache Details section on the Procedure Cache tab of the Memory Detail:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Type</td>
<td>The type of object (ad hoc SQL, etc.)</td>
</tr>
<tr>
<td>Cache Type</td>
<td>The category of SQL code inside the cache (executable plan, etc.)</td>
</tr>
<tr>
<td>Object ID</td>
<td>The numeric ID of the object.</td>
</tr>
<tr>
<td>Object Name</td>
<td>The name of the object (if applicable).</td>
</tr>
<tr>
<td>Database ID</td>
<td>The numeric ID of the database.</td>
</tr>
<tr>
<td>Database</td>
<td>The database where the code originated.</td>
</tr>
<tr>
<td>User ID</td>
<td>The numeric ID of the user.</td>
</tr>
<tr>
<td>User</td>
<td>The owner of the object or code.</td>
</tr>
<tr>
<td>Use Count</td>
<td>The number of uses for the object.</td>
</tr>
<tr>
<td>SQL Bytes</td>
<td>The amount of SQL bytes used by the code object.</td>
</tr>
<tr>
<td>Size (KB)</td>
<td>The size used by the object in kilobytes.</td>
</tr>
<tr>
<td>SQL</td>
<td>The actual SQL statement or code being executed.</td>
</tr>
</tbody>
</table>

Location: [Microsoft SQL Server Performance Analyst Statistics](#) > Memory View (SQL Server Performance Analyst) > Procedure Cache Tab

Metrics: Seeing many objects of the ad hoc SQL type might indicate an environment where sessions are submitting a lot of SQL requests. Many SQL Server DBAs like to control code submissions through stored procedures.

### Log Cache Tab

The Log Cache tab includes the following sections:

- [Database Log Cache Ratios](#)
- [Log Cache Details](#)

The following statistic, available on this page, duplicates a statistic on the [Key Ratio Analysis Pane](#) of the [Home View (SQL Server Performance Analyst)](#) page:

- [Log Cache Hit Ratio](#)
Database Log Cache Ratios

The Log Cache Hit Ratio statistic represents the percentage of log cache reads satisfied from the log cache. The database log cache ratios display breaks down log cache hit ratios by database. Note that some databases with inactive logs will not display a log cache hit ratio.

Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Log Cache Tab

Correction A low percentage on this statistic is not necessarily a bad sign, as it is possible that the information needed from the log will not be readily available in memory.

Log Cache Details

Before ever writing transactions to disk, the log manager of SQL Server formats everything in memory. This area of memory is known as the log cache. The log writer of SQL Server moves through the log caches when transactions are committed (as well as other events) and flushes each cache out to disk. SQL Server also reads from the cache when log records are needed. The table below describes the information available in the Log Cache Details section on the Log Cache tab of the Memory Detail:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>The name of the SQL Server database.</td>
</tr>
<tr>
<td>Log Cache Reads</td>
<td>The number of reads from the log cache.</td>
</tr>
<tr>
<td>Log Flushes</td>
<td>The number of times data was flushed from the log to disk.</td>
</tr>
<tr>
<td>Log Flush Waits</td>
<td>The number of times the log had to wait before flushing data to disk.</td>
</tr>
<tr>
<td>Log Flush Wait Time</td>
<td>The amount of time the log waited before flushing data to disk in milliseconds.</td>
</tr>
<tr>
<td>Log Growths</td>
<td>The number of times the log had to physically grow in size to meet the need for more space.</td>
</tr>
<tr>
<td>Log Shrinks</td>
<td>The number of times the log contracted in physical size.</td>
</tr>
</tbody>
</table>
Location  Microsoft SQL Server Performance Analyst Statistics > Memory View (SQL Server Performance Analyst) > Log Cache Tab

Metrics  Seeing high amounts of wait time for log flushes could indicate a bottleneck at the disk level. A log that shows high number of growths likely indicates an undersized log. While automatic growth can alleviate out-of-space conditions, many growth operations can slow down overall operations. It is better to have a properly sized transaction log that allows SQL Server to continually enlarge it in size when needed.

Correction  Consider relocating logs showing high amounts of wait time to faster disks. For logs showing high numbers of growths, permanently enlarge the log(s) via an ALTER DATABASE command that will resize the log files.
I/O View (SQL Server Performance Analyst)

In addition to a Home page, the I/O category of SQL Server Performance Analyst includes the following tabbed pages:

- Database I/O Tab
- File Tab
- System I/O Tab
- User I/O Tab

Home

The Home page of the I/O category includes statistics in the following categories:

- Bottleneck Analysis Pane
- I/O Access Patterns
- Key System Analysis Pane
- SQL Analysis Pane
- Workload Analysis Pane

Key System Analysis Pane

When complaints begin to surface about your database's performance, oftentimes the root cause can be traced to one or more issues with I/O. The thing to keep in mind when you begin to monitor the I/O of your database is that you are actually reviewing the success of your physical design model.

All the physical storage characteristics and placements, the table and index designs, and the speed that it all works are on display when I/O is monitored. Because a database's main index of performance is measured by how fast I/O needs are satisfied, it is your responsibility to quickly interrogate SQL Server to determine if a reported database slowdown is I/O related.

The following key I/O values are reported in this section:

- Checkpoint Pages
- Lazy Writes
- Log Cache Reads
- Log Flushes
- Workload Analysis Pane
Page Reads

This metric represents that number of physical database page reads that are issued per second by SQL Server.

Location  Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > Home > Key System Analysis Pane

Metrics  Page reads are to be expected, especially after initial server start up. This is because SQL Server must first satisfy requests for data and meta-data by reading information in from physical disk. Numerous page reads can also be expected if the physical server does not contain an adequate amount of memory to hold repetitively requested blocks of information. No hard-and-fast rules exist for how many page reads per second is too much. You can cross-reference this statistic with the physical server disk statistics to see if physical page reads and accompanying physical disk I/O is approaching the server’s premium capacity levels. And because logical I/O is always many times faster than physical I/O, you should also evaluate the buffer cache hit ratio to determine overall memory vs. physical read efficiency.

Correction  If you find that the server is becoming overworked from a physical I/O standpoint, there are several courses of action you can take: Examine index usage to ensure that unnecessary table scans are not occurring. Check the physical database design to see if table objects have been over-normalized. Ensure that SQL Server is configured to use sufficient amounts of memory. Examine the min server memory (MB) and max server memory (MB) parameters to see if SQL Server is constrained on either end of the memory spectrum. Check for large pinned table objects that could be using excessive amounts of space in the buffer cache. Last, but not least, investigate the possibility of adding more RAM to the physical server.

Page Writes

The Page Writes statistic represents the number of physical database page writes issued by SQL Server. Page Writes take place during operations such as checkpoints, lazywriter writes, index creations, and BCP routines.
Metrics  Page Writes can give you an idea of overall physical write activity, however there are a number of statistics that pertain specifically to certain write activities like checkpoints, etc., that you can examine to determine the amount of physical writes caused by distinct SQL Server processes. With respect to performance, response times experienced by SQL Server users are normally not impacted by write operations unless the writes are synchronous in nature. These are typically BCPs, database recovery operations, and index creations.

Read Ahead Pages

The Read Ahead Pages statistic represents the number of physical database page read in anticipation of use by SQL Server. If SQL Server senses that database pages are being read in a sequential manner, it will institute a pre-fetch mechanism that moves pages into the buffer cache before they are actually needed by a process.

Metrics  If data is accessed sequentially (for example, through the use of a clustered index), the read ahead mechanism of SQL Server can increase performance by needed database pages already in the buffer cache before they are actually requested. However, because the read ahead mechanism is typically triggered by full table or index range scans, if the read ahead pages are actually required to satisfy a user’s query, then performance might actually suffer. In these cases, the judicious use of indexes is a better route to take.

Log Flushes

The Log Flushes statistic represents the total number of log pages for all databases written to disk by the log writer process. A log flush occurs when SQL Server writes all changes from the database’s log cache out to the database’s log files on disk.

Metrics  Increasing numbers observed for log flushes should not cause concern unless the I/O subsystem of the server appears overwhelmed. In addition, to minimize I/O contention between a database and its accompanying log, it is wise to place database files and log files on separate disks.

Correction  If you have placed a very active database on the same physical file as its log, you can look into moving the log to a separate physical device by adding new log files to a new drive and subsequently removing the old log files when they are not being used.

Log Cache Reads

The Log Cache Reads statistic represents the reads performed per second through the log manager cache. Before ever writing transactions to disk, the log manager of SQL
Server formats them in memory. This area of memory is known as the log cache and only contains log records. The log writer of SQL Server moves through the log caches when transactions are committed (as well as other events) and flushes each cache out to disk.

**Location** Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > Home > Key System Analysis Pane

### Checkpoint Pages

The Checkpoint Pages statistic represents the number of pages flushed to disk per second by a checkpoint or other operation that require all dirty (modified) pages to be flushed.

**Location** Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > Home > Key System Analysis Pane

**Metrics**

- Checkpoint operations are used by SQL Server to minimize the amount of work the server must perform when databases are recovered during system startup. Checkpoints periodically write out modified pages that are found in the buffer cache to disk. After, SQL Server records the operation in the log to signify that the operation succeeded. Checkpoints can be explicitly performed by a database owner issuing the checkpoint command. SQL Server also performs checkpoints automatically for databases that have the trunc log on chkpt option set. Large SQL Servers have the potential to generate lots of checkpoint write operations. Although SQL Server will do what it can to minimize checkpoint activity, you can also set the recovery interval server parameter to influence how often checkpoints should run.

**Correction** If you believe excessive checkpoint activity is occurring, you can take the following steps: Set the recovery interval server parameter to a larger value with `sp_configure`. Restart SQL Server so the change will take affect or use the `RECONFIGURE` option to make the change immediately.

### Lazy Writes

The lazy writer is a SQL Server system process that flushes out batches of dirty and aged buffers (buffers that contain changes that must be written back to disk before the buffer can be reused for a different page) and make them available to user processes. The Lazy Writes statistic represents the number of buffers written by the buffer manager’s lazy writer process.

**Location** Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > Home > Key System Analysis Pane

**Metrics**

- High values might indicate a thrashing situation with data scanned into the buffer cache (but referenced seldom) and then immediately moved back out.

### Bottleneck Analysis Pane

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall
scheme of things or it can be an indicator that a database bottleneck exists. And this is where wait-based or bottleneck analysis comes into play. DBAs use this form of performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance: it helps you track where a database has been spending its time. The Performance Analyst I/O home page identifies the top I/O related waits that might be currently causing performance issues. Also included are the current hottest database/log files and a summary of I/O activity.

Bottleneck Analysis includes the following information:

- **I/O Errors**
- **Hottest Database/Log Files**
- **Total I/O**
- **Top I/O Waits**

The following statistic, available on this pane, duplicates a statistic on the Key Ratio Analysis Pane of the Home View (SQL Server Performance Analyst) page:

- **I/O Busy**

## I/O Errors

I/O Error Rate reflects total number of I/O errors (errors during read and write operations) encountered by the server since the last refresh inside Performance Analyst Center. I/O Error Rate is a percentage based on Total I/O (the sum the physical reads and writes).

**Location** Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics** You should observe few, if any errors.

**Correction** If you notice any errors, you should check the SQL Server error log for details.

## Hottest Database/Log Files

The Hottest Database/Log Files display presents the most active database files as indicated by physical I/O activity (reads and writes).
I/O View (SQL Server Performance Analyst)

Location Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics Understanding the storage-level hot spots of a database is beneficial for a couple of reasons. First, you can get a feel for overworked physical disks by viewing I/O statistics at the tablespace and datafile levels. If a particular disk or set of disks is under too much strain, you attempt to relocate the databases to other less-used devices or create new file groups on different disks and move hot objects to them (assuming, of course, you have extra disks available). Second, if you have used standard DBA practice and placed indexes in their own file group, you can view the I/O statistics for that file group and see if the indexes are actually being used.

Correction Some areas to consider when viewing the hottest database files display are: Seeing a lot of activity in the master database and datafiles might indicate a lot of recursive calls. The tempdb database (devoted to sort activity) shows higher volumes of physical I/O which could indicate a problem with excessive disk sorts. You might want to quickly review all the physical I/O for each drive/file system and get a idea of the overworked disks on your server. If you have under-utilized disk drives (with their own controllers), you should consider relocating some databases or filegroups that exhibit high I/O characteristics to those drives. To minimize contention at the physical disk level, and improve performance overall, it is generally recommended that a SQL Server database have its database and log files physically separated onto different drives.

Total I/O

The Total I/O statistic represents the total number of physical reads and writes.

Location Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Top I/O Waits

The Top I/O Waits statistics rank the top I/O related waits by wait time.

Correction Wait events can be hard to interpret at times. If you see a particular event that has caused a lot of wait time, you can review the information in this link (Microsoft Knowledge Base Article - 244455) to help understand the cause and potential remedy: http://support.microsoft.com/default.aspx?scid=kb;en-us;Q244455

SQL Analysis Pane

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured server down in terms of end-user response times.

Before you can identify problem SQL in your database, you have to ask the question - “What is bad SQL?” What criteria do you use when you begin the hunt for problem SQL
in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every SQL Server professional’s satisfaction. The table below lists some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reads (Physical)</td>
<td>This is often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user’s request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at a statements’ logical I/O as well.</td>
</tr>
<tr>
<td>Writes</td>
<td>These can be caused by DML activity (INSERTs, etc.), but writes can also be indicative of heavy disk sort activity.</td>
</tr>
</tbody>
</table>

There are other criteria that you can examine like sort activity or access plan statistics (that show items like Cartesian joins and the like), but more often than not, these measures are reflected in the criteria listed above.

The SQL Analysis section provides you with a quick overview of the percentage of Reads, Writes, CPU, and Elapsed Time the most expensive SQL statements tracked by Performance Analyst have used. Depending on the page you are on, you might just see information regarding physical I/O activity or DML statements. For example, you might see that a SQL statement has caused 60% of all physical reads on the system, or that a procedure is responsible for 90% of all the CPU usage. To get information regarding the actual SQL text or stored procedure calls, drill down into the Top SQL details views.

**Note:** SQL Profiling is turned on by default in Performance Analyst so you can automatically collect SQL traffic. If you do not want to collect SQL execution information, use the options inside of Performance Analyst to disable SQL profiling.

**Metrics**

When you begin to look for inefficient SQL in a database, there are two primary questions you should answer:

- What has been the worst SQL that has historically been run in my database?
- What is the worst SQL that is running right now in my database?

When correcting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It might be that the query is in an inefficient Transaction SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.
There is the possibility that the SQL statement just is not tuned well. To determine that, you can drill down further into the Performance Analyst Top SQL view and begin working with the query through EXPLAIN plan analysis and other techniques inside Embarcadero’s DBArtisan.

**I/O Access Patterns**

There are many different routes that SQL Server can take to access various objects contained in a database. The I/O Access Patterns display summarizes the methods SQL Server is using to satisfy end-user requests for data.

**Location**

Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > Home > SQL Analysis Pane

**Metrics**

Depending on the version of SQL Server you are using, expect to deal with different access styles. The table below describes some of the SQL Server access styles:
<table>
<thead>
<tr>
<th>Access Style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full Scans</td>
<td>Full Scans are the total number of full table or index scans. Full scans occur if a table is inadequately indexed or if SQL Server needs to access all rows in a table or index to satisfy a query. Other operations that can cause full scans include UPDATE STATISTICS calls. Avoid unnecessary scans on large tables is something to avoid, and can be a signal to you as a DBA to investigate the use of more indexes and to review SQL access through EXPLAIN plans. Small table scans are efficient because SQL Server can often cache the entire table in a single I/O operation. Large numbers of index scans are normally desirable too, since it typically indicates the fastest possible resolution to data access requests.</td>
</tr>
<tr>
<td>Range Scans</td>
<td>Range Scans are the total number of qualified range scans through indexes. Large numbers of index scans are normally desirable, since it typically indicates the fastest possible resolution to data access requests is being taken.</td>
</tr>
<tr>
<td>Probe Scans</td>
<td>Probe scans are used in SQL Server to directly find rows in an index or base table. Large numbers of probe scans are normally desirable, since they typically indicate the fastest possible resolution to data access requests is being taken.</td>
</tr>
<tr>
<td>Index Searches</td>
<td>Index searches are normally used to start range scans, for single index record fetches and also might be used to reposition an index.</td>
</tr>
<tr>
<td>Forward Record Fetches</td>
<td>The Forwarded Record Fetches statistic represents the total number of records fetched by reading forwarded record pointers. SQL Server will move rows in a table under certain conditions. One situation might arise when you update a row in a table that has a variable-length column to a larger size that will no longer fit on its original page. Another situation would be if SQL Server moves a row when the clustered index column changes. When SQL Server creates a forwarding pointer, it remains in place unless one of two things happens. The first is when a row shrinks enough to move back to its original location. The second is when the entire database shrinks. When a database file shrinks, SQL Server will reassign the row identifiers, which are used as the row locators, so the shrink process never generates forwarded rows. Forwarded records can reduce performance at times because additional I/O is involved to first obtain the record pointer to the relocated row, and then the row itself is read.</td>
</tr>
</tbody>
</table>

**Correction**

Actions to take after observing the ways SQL Server is accessing data depend on the actual situation you witness. If consistent numbers are present for Forward Record Fetches, you might want to examine your databases to see which tables have forwarded records. You can easily do this by utilizing the Embarcadero Space Analyst to view forwarded record data for tables.

If you do not have Space Analyst, then to see the total count of forwarded records in a table, you can enable trace flag 2509, and then execute the DBCC CHECKTABLE command. The output should display the number of forwarded records in that table. Tables with many forwarded records could be candidates for table reorganization.

Here are some methods you can use to avoid unnecessary full scans:
Try not to use SQL statements that include the NOT IN, NOT LIKE, <>, IS NULL operators since they typically suppress the use of indexes.

When referencing concatenated indexes with queries, be sure the leading column in the index is used. If it is not, the index will not be used at all.

Avoid using functions in WHERE predicates.

Workload Analysis Pane

It is not uncommon for one or two users to cause the majority of runtime problems plaguing a database. The problem could be a runaway process, an untuned batch procedure, or other user-initiated operation. The Top I/O Hogs display showcases the top sessions that have caused the most physical I/O on the system (both reads and writes).

Metrics

If you see one or two users who have caused more than 25-50% of total I/O, then you should drill down further into the sessions to see what activities they are performing.

System I/O Tab

The System I/O tab of the I/O Detail includes the following sections:

- AWE I/O
- I/O Activity
- Physical I/O
- Space I/O

Physical I/O

SQL Server performs many system-related I/O functions to keep data moving into and out of the server. The System I/O tab of the I/O Detail displays statistics that track various system-related I/O operations. The Physical I/O section details I/O tasks that involve physical disk activity. The table below describes the information available in the Physical I/O section:
<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Page Reads</td>
<td>The number of physical database page reads that are issued per second by SQL Server. It is collective in nature, meaning that it represents the total page reads per second across all databases that exist on the target SQL Server.</td>
</tr>
<tr>
<td>Page Writes</td>
<td>The number of physical database page writes issued by SQL Server. Page Writes take place during operations such as checkpoints, lazy writer writes, index creations, and BCP routines.</td>
</tr>
<tr>
<td>Checkpoint Pages</td>
<td>The number of pages flushed to disk per second by a checkpoint or other operation that require all dirty (modified) pages to be flushed.</td>
</tr>
<tr>
<td>Lazy Writes</td>
<td>The number of buffers written by the buffer manager’s lazy writer. The lazy writer is a system process that flushes out batches of dirty and aged buffers and makes them available to SQL Server processes. The lazy writer eliminates the need to perform frequent checkpoints in order to create available buffers.</td>
</tr>
<tr>
<td>Read Ahead Pages</td>
<td>The number of physical database pages read in anticipation of use by SQL Server. If SQL Server senses that database pages are being read in a sequential manner, it institutes a pre-fetch mechanism that moves pages into the buffer cache before they are actually needed by a process.</td>
</tr>
<tr>
<td>Page Lookups</td>
<td>The number of requests to find a page in the buffer pool.</td>
</tr>
</tbody>
</table>
I/O View (SQL Server Performance Analyst)

Location  
Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > System I/O Tab

Metrics  
Page reads are to be expected, especially after initial server start up. SQL Server must first satisfy requests for data and metadata by reading information in from physical disk. Numerous page reads can also be expected if the physical server does not contain an adequate amount of memory to hold repetitively requested blocks of information.

No hard and fast rules exist for how many page reads per second is too much. You can cross reference this statistic with the physical server disk statistics to see if physical page reads and accompanying physical disk I/O is approaching the server’s premium capacity levels. And because logical I/O is always many times faster than physical I/O, you should also evaluate the buffer cache hit ratio to determine overall memory vs. physical read efficiency. Page Writes can give you an idea of overall physical write activity. There are a number of statistics, however, that pertain specifically to certain write activities like checkpoints, that can be examined to determine the amount of physical writes caused by distinct SQL Server processes.

With respect to performance, response times experienced by SQL Server users are normally not impacted by write operations unless the writes are synchronous in nature. These are typically BCPs, database recovery operations, and index creations. With respect to read ahead pages, If data is accessed sequentially (for example, through the use of a clustered index), the read ahead mechanism of SQL Server can increase performance by needed database pages already in the buffer cache before they are actually requested. However, because the read ahead mechanism is typically triggered by full table or index range scans, if the read ahead pages are actually required to satisfy a user’s query, performance can actually suffer. In these cases, the judicious use of indexes is a better route to take. Checkpoint operations are used by SQL Server to minimize the amount of work the server must perform when databases are recovered during system startup. Checkpoints periodically write out modified pages that are found in the buffer cache to disk. Afterward, SQL Server records the operation in the log to signify that the operation succeeded. A database owner issuing the checkpoint command can explicitly perform checkpoints. SQL Server also performs checkpoints automatically for databases that have the trunc log on chkpt option set. Large SQL Servers have the potential to generate lots of checkpoint write operations. Although SQL Server minimizes checkpoint activity, you can also set the recovery interval server parameter to influence how often checkpoints can run.

Correction  
If you find that the server is becoming overworked from a physical I/O standpoint, here are a few things you can do: Examine index usage to ensure that unnecessary table scans are not occurring. Check the physical database design to see if table objects have been over-normalized. Ensure that SQL Server is configured to use sufficient amounts of memory. Examine the min server memory (MB) and max server memory (MB) parameters to see if SQL Server is constrained on either end of the memory spectrum. Check for large pinned table objects that could be using excessive amounts of space in the buffer cache. Last, but not least, investigate the possibility of adding more RAM to the physical server. If you believe excessive checkpoint activity is occurring, you can take the following steps: Set the recovery interval server parameter to a larger value with sp_configure. Restart SQL Server or use the RECONFIGURE option to make the change immediately.

Space I/O
SQL Server performs many system-related I/O functions to keep data moving into and out of the server. The Space I/O section of the I/O Detail details space-related I/O operations. The table below describes the information available in the Space I/O section:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extents Allocated</td>
<td>The number of space extents that SQL Server allocated. Rapidly increasing numbers for these statistics indicates that SQL Server is receiving large volumes of incoming data and is allocating space to make room.</td>
</tr>
<tr>
<td>Extent Deallocations</td>
<td>This indicates that SQL Server is reclaiming space from database objects due to shrinking database volumes.</td>
</tr>
<tr>
<td>Freespace Page Fetches</td>
<td>The number of pages by free space scans used to satisfy requests to insert record fragments.</td>
</tr>
<tr>
<td>Freespace Scans</td>
<td>The number of scans performed by SQL Server to locate free space for an incoming record.</td>
</tr>
<tr>
<td>Mixed Page Allocations</td>
<td>The number of pages allocated from mixed extents. These are used for storing the first eight pages that are allocated to an index or table.</td>
</tr>
<tr>
<td>Page Deallocations</td>
<td>This indicates that SQL Server is reclaiming space from database objects due to shrinking database volumes.</td>
</tr>
<tr>
<td>Page Splits</td>
<td>When data is inserted or updated in a table, SQL Server might reorganize the storage of the data in the table's index pages. When an index page becomes full, but a DML operation demands room on that page, SQL Server moves about half the rows to a new page to accommodate the request. This reorganization is known as a page split. Performance for DML actions can be impaired from page split operations. In addition, more index pages can make for longer index scan times.</td>
</tr>
</tbody>
</table>

**Location**  
Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > System I/O Tab

**Metrics**  
Increasing numbers for extent and page allocation, and freespace operations likely indicates aggressive volumes of data being inserted or modified in SQL Server. Page splits cause additional overhead in the form of CPU usage and I/O. Observing large numbers of page splits can signal a resource bottleneck in your server.

**Correction**  
To avoid page splits, you can look into tuning the FILLFACTOR property of an index, which controls the percentage of the index page that is filled during creation. The default, 100, tells SQL Server to completely fill each page, whereas lower numbers tell SQL Server to leave room for additional index rows or updates to existing rows.

**I/O Activity**

SQL Server performs many system-related I/O functions to keep data moving into and out of the server. The I/O Activity section of the I/O Detail details maintenance-related
I/O operations. The table below describes the information available in the I/O Activity section:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBCC Logical Scans</td>
<td>The number of logical read scan bytes per second caused by DBCC operations.</td>
</tr>
<tr>
<td>Bulk Copy Rows</td>
<td>The number of rows copied either into or out of the database via the BCP utility.</td>
</tr>
<tr>
<td>Bulk Copy Throughput</td>
<td>The amount of data (in KB) copied via BCP operations.</td>
</tr>
<tr>
<td>Transactions</td>
<td>The number of transactions that have occurred within the database.</td>
</tr>
<tr>
<td>Log Flushes</td>
<td>The number of log flushes for the server.</td>
</tr>
<tr>
<td>Backup/Restore T-Put</td>
<td>Defines the read/write throughput for backup and restore operations.</td>
</tr>
</tbody>
</table>

Location: Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > System I/O Tab

### AWE I/O

SQL Server performs many system-related I/O functions to keep data moving into and out of the server. The AWE I/O section of the I/O Detail details I/O relating to Address Windowing Extensions (the SQL Server mechanism for supporting very large amounts of RAM). The table below describes the information available in the AWE I/O section:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lookup Maps</td>
<td>The number of times that a database page was requested by the server, found in the buffer pool, and mapped. When it is mapped, it is made a part of the server's virtual address space.</td>
</tr>
<tr>
<td>Stolen Maps</td>
<td>The number of times that a buffer was taken from the free list and mapped.</td>
</tr>
<tr>
<td>Unmap Cells</td>
<td>The number of calls to unmap buffers. When a buffer is unmapped, it is excluded from the virtual server address space. One or more buffers might be unmapped on each call.</td>
</tr>
<tr>
<td>Unmap Pages</td>
<td>The number of SQL Server buffers that are unmapped.</td>
</tr>
<tr>
<td>Write Maps</td>
<td>The number of times that it is necessary to map in a dirty buffer so it can be written to disk.</td>
</tr>
</tbody>
</table>
User I/O Tab

The User I/O tab of the I/O Detail includes the following sections:

- **Lock Activity**
- **SQL Activity**
- **Temporary Object Activity**
- **User Object Activity**

User Object Activity

The User Object Activity section of the I/O Detail displays statistics that track various user-related I/O operations. The I/O function along with its counter value is presented. The User Object Activity section details performance statistics that reflect how SQL Server is performing object access operations. The table below describes the information available in the User Object Activity section:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Forwarded Records</td>
<td>The number of records per second fetched through forwarded record pointers.</td>
</tr>
<tr>
<td></td>
<td>At times forwarded records can reduce performance because additional I/O is</td>
</tr>
<tr>
<td></td>
<td>involved to first obtain the record pointer to the relocated row, and then</td>
</tr>
<tr>
<td></td>
<td>the row itself is read.</td>
</tr>
<tr>
<td>Full Scans</td>
<td>Full scans of moderately sized indexes or tables are generally okay. SQL</td>
</tr>
<tr>
<td></td>
<td>Server can scan and cache a small table much faster than using its index to</td>
</tr>
<tr>
<td></td>
<td>navigate to any requested data. Full, unrestricted, large table scans,</td>
</tr>
<tr>
<td></td>
<td>however, are typically not good and degrade overall system performance and</td>
</tr>
<tr>
<td></td>
<td>response time.</td>
</tr>
<tr>
<td>Index Searches</td>
<td>The total number of index searches per second. Index searches are normally</td>
</tr>
<tr>
<td></td>
<td>used to start range scans, for single index record fetches and can be used</td>
</tr>
<tr>
<td></td>
<td>to reposition an index.</td>
</tr>
<tr>
<td>Probe Scans</td>
<td>The total number of probe scans per second. Probe scans are used in SQL</td>
</tr>
<tr>
<td></td>
<td>Server to directly find rows in an index or base table.</td>
</tr>
<tr>
<td>Range Scans</td>
<td>The total number of qualified range scans through indexes per second.</td>
</tr>
<tr>
<td>Skipped Ghosted Records</td>
<td>The number of ghosted records per second skipped during scans.</td>
</tr>
</tbody>
</table>
Metrics

Full scans occur if a table is inadequately indexed or if SQL Server truly needs to access all rows in a table or index to satisfy a query. UPDATE STATISTICS calls can also cause full scans. Unnecessary scans on large tables is something to avoid, and can be a signal to you as a DBA to investigate the use of more indexes and to review SQL access through EXPLAIN plans. Small table scans are actually a good thing because SQL Server can often cache the entire table in a single I/O operation. Large numbers of index scans are normally desirable too, because this typically indicates the fastest possible resolution to data access requests.

When SQL Server creates a forwarding pointer, it remains in place unless one of two things happens. The first is when a row shrinks enough to move back to its original location. The second is when the entire database shrinks. When a database file shrinks, SQL Server reassigns the row identifiers, which are used as the row locators, so the shrink process never generates forwarded rows. Forwarded records can reduce performance at times because additional I/O is involved to first obtain the record pointer to the relocated row, and then the row itself is read. Large numbers of index searches and probe scans are normally desirable because they typically indicate the fastest possible resolution to data access requests.

Correction

Here are some methods you can use to avoid unnecessary large table scans: Try not to use SQL statements that include the NOT IN, NOT LIKE, <>, IS NULL operators because they typically suppress the use of indexes. When referencing concatenated indexes with queries, be sure the leading column in the index is used. If it is not, the index will not be used at all. Avoid using functions in WHERE predicates. If consistent numbers are present for Forward Record Fetches, examine your databases to see which tables have forwarded records. This can easily be done with the Embarcadero Space Analyst component. If you do not have Space Analyst, then to see the total count of forwarded records in a table, enable trace flag 2509, and then execute the DBCC CHECKTABLE command. The output should display the number of forwarded records in that table. Tables with many forwarded records could be candidates for table reorganization.

SQL Activity

The SQL Activity section of the User I/O tab of the I/O Detail displays statistics that track various user-related I/O operations. The I/O function along with its counter value is presented. The SQL Activity section details performance statistics that reflect SQL I/O-related operations. The table below describes the information available in the SQL Activity section:
<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto-Param Attempts</td>
<td>Auto-parameterization occurs when an instance of SQL Server attempts to reuse a cached plan for a previously executed query that is similar to, but not the same as, the current query. The Auto-param Attempts statistic shows the number of auto-parameterization attempts per second and includes failed, safe, and unsafe auto-parameterizations.</td>
</tr>
<tr>
<td>Batch Requests</td>
<td>A batch is a collection of one or more SQL statements sent in one unit by the client. Each batch is compiled into a single execution plan. If the batch contains multiple SQL statements, all of the optimized steps needed to perform all the statements are built into a single execution plan. The Batch Requests statistic shows the number of batch requests per second that are processed by the SQL Server instance.</td>
</tr>
<tr>
<td>Failed Auto-Params</td>
<td>Auto-parameterization occurs when an instance of SQL Server attempts to reuse a cached plan for a previously executed query that is similar to, but not the same as, the current query. The Failed Auto-params statistic shows the number of failed auto-parameterization attempts per second.</td>
</tr>
<tr>
<td>Safe Auto-Params</td>
<td>Auto-parameterization occurs when an instance of SQL Server attempts to reuse a cached plan for a previously executed query that is similar to, but not the same as, the current query. The Safe auto-params statistic shows the number of auto-parameterization attempts per second and includes only safe auto-parameterizations (ones where the cached plan can be shared).</td>
</tr>
<tr>
<td>Scan Point Revalidations</td>
<td>The number of times per second that the scan point had to be revalidated to continue the scan.</td>
</tr>
<tr>
<td>SQL Compilations</td>
<td>The number of SQL compilations performed, indicating the number of times the compile code path is entered. This also includes compiles due to recompiles. When SQL Server user activity levels become stable, this value reaches a steady state.</td>
</tr>
<tr>
<td>SQL Re-Compilations</td>
<td>The total number of recompiles triggered per second in a SQL Server instance. Recompiles occur when SQL Server determines that the currently defined execution plan for an executing stored procedure might no longer be the best possible plan. SQL Server pauses the query execution and recompiles the stored procedure.</td>
</tr>
<tr>
<td>Unsafe Auto-Params</td>
<td>Auto-parameterization occurs when an instance of SQL Server attempts to reuse a cached plan for a previously executed query that is similar to, but not the same as, the current query. The Unsafe auto-params statistic shows the number of auto-parameterization attempts per second and includes only safe auto-parameterizations (ones where the cached plan cannot be shared).</td>
</tr>
</tbody>
</table>
Location  Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > User I/O Tab

Metrics  SQL Server’s ability to match new SQL statements with existing, unused execution plans is increased when parameters or parameter markers are used in Transact-SQL statements. If an SQL statement is executed without parameters, SQL Server parameterizes the statement internally to increase the possibility of matching it against an existing execution plan. A high number for auto-param attempts shows that SQL Server is efficiently reusing existing cached plans. A small number for failed auto-param attempts shows that SQL Server is efficiently reusing existing cached plans. Because compilation is a significant part of a query’s turnaround time, you should strive to have as many compilations stored in the cache as possible. If this number does not stabilize in direct proportion to user activity stabilizing, you should investigate your SQL Cache to see if it has adequate memory assigned to it. Recompiles slow down the process that is executing the procedure and increases the load on the CPU. By extension, the more recompiles that are occurring on your system, the more overall load increases resulting in poor performance. In general, you want to keep the number of recompiles low. The most common reasons SQL Server would issue a recompile are: Running sp_recompile against any table referenced in the stored procedure. Significant data changes in a referenced table. Schema changes to referenced objects. The use of the WITH RECOMPILE clause in the CREATE PROCEDURE or EXECUTE statement. A plan no longer available in the system cache.

Correction  For failed auto-param attempts, you can increase the ability of the relational engine to match complex SQL statements to existing, unused execution plans, by explicitly specify the parameters using either sp_executesql or parameter markers in your T-SQL code. For high numbers of SQL re-compilations, try to practice coding standards that eliminate the most frequent causes detailed above. Also, try to: Use temporary tables only in the stored procedure that created them. Minimize creating temporary tables in control block structures. Use the KEEP PLAN option on references to static temporary tables. Issue the CREATE TABLE statement before any other references to the created table. Minimize the use of temporary tables.

Lock Activity

The Lock Activity section of the User I/O tab of the I/O Detail displays statistics that track various user-related I/O operations. The I/O function along with its counter value is presented. The Lock Activity section details performance statistics that reflect how SQL Server is handling lock operations. The table below describes the information available in the Lock Activity section:
<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Lock Escalations</td>
<td>The number of times locks on a table were escalated.</td>
</tr>
<tr>
<td>Locks</td>
<td>The total number of locks acquired on the server.</td>
</tr>
<tr>
<td>Blocked Users</td>
<td>The users currently being blocked by other processes.</td>
</tr>
<tr>
<td>Deadlocks</td>
<td>The number of deadlocks detected by SQL Server. Page Deadlocks occur when processes cannot proceed because they are waiting on a set of resources held by each other or held by other processes.</td>
</tr>
</tbody>
</table>
Locations: Microsoft SQL Server Performance Analyst Statistics > I/O View (SQL Server Performance Analyst) > User I/O Tab

Metrics: Many table lock escalations could indicate contention problems. If increasing numbers of table lock escalations are viewed at the same time as blocking or deadlock problems, the application design could be at fault. Consistently seeing positive numbers for the blocked statistic should also clue you into the fact that a bottleneck exists for some processes. You can easily drill down and discover the exact process(es) holding locks that are blocking out other user activity. Another situation to look for with respect to locking is when the total number of acquired locks reaches the maximum lock limit currently set on SQL Server. Consistently seeing page deadlock counts greater than zero indicates that some user processes are experiencing delays completing their work. When SQL Server identifies a page deadlock, it resolves the situation by choosing the process that can break the deadlock. This process is termed the deadlock victim. SQL Server rolls back the deadlock victim’s transaction, and then notifies the process’ application by returning an error message. It also cancels the process’ request and allows the transactions of the remaining processes to continue. SQL Server always attempts to choose the least expensive thread running the transaction as the deadlock victim.

Correction: Once discovered, a blocking lock situation can normally be quickly remedied - the DBA issues a KILL against the offending process, which eliminates the stranglehold on the objects the user was accessing. Other user processes then almost always complete in an instant. Discovering the blocked lock situation is made easier by using tools like Embarcadero Performance Analyst, but preventing the blocking lock situation in the first place is tricky. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. By default, all processes wait indefinitely for locks in SQL Server. You can change this behavior by using the SET LOCK_TIMEOUT command, which limits the number of seconds that a process waits for a lock before timing out. Because SQL Server automatically resolves deadlock situations, you should work proactively to prevent them in the first place. You can change default deadlock behavior by using the SET DEADLOCK_PRIORITY command, which reprioritizes a process’ position in a deadlock situation.

Temporary Object Activity

The Temporary Object Activity section of the User I/O tab of the Users Detail displays statistics that track various user-related I/O operations. The I/O function along with its counter value is presented. The Temporary Object Activity section details performance statistics that reflect how SQL Server is handling the creation of temporary objects, such as temporary tables used in stored procedures. The table below describes the information available in the Temporary Object Activity section:
<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Workfiles Created</td>
<td>The number of work files created by SQL Server.</td>
</tr>
<tr>
<td>Worktables Created</td>
<td>The total number of work tables created. Worktables are used many times by SQL Server to perform a logical operation specified in an end-user SQL statement. GROUP BY, ORDER BY, or UNION queries can cause worktables to be created as can specific CREATE statements used in Transact SQL processing. Worktables are built in the tempdb database and are dropped automatically at the end of the statement or procedure run.</td>
</tr>
</tbody>
</table>

Location [Microsoft SQL Server Performance Analyst Statistics](#) > I/O View (SQL Server Performance Analyst) > User I/O Tab

Metrics With respect to worktables, keep in mind that the tempdb database should be large enough to hold large worktables.

Database I/O Tab

The Database I/O tab of the I/O Detail includes the following sections:

- Database Bytes Read/Write Summary
- Database Read/Write Summary

Database Read/Write Summary

The Reads statistic represents that number of physical database page reads that are issued per second by SQL Server. The Writes statistic represents the number of physical database page writes issued by SQL Server. Writes take place during operations such as checkpoints, lazywriter writes, index creations, and BCP routines. Both statistics are collective in nature, meaning that they represent the total page reads and writes across all databases that exist on the target SQL Server.
Page reads are to be expected, especially after initial server start up. This is because SQL Server must first satisfy requests for data and metadata by reading information from physical disk. Numerous page reads can also be expected if the physical server does not contain an adequate amount of memory to hold repetitively requested blocks of information. No hard-and-fast rules exist for how many page reads per second is too much. You can cross reference this statistic with the physical server disk statistics to see if physical page reads and accompanying physical disk I/O is approaching the server's premium capacity levels. And because logical I/O is always many times faster than physical I/O, you should also evaluate the buffer cache hit ratio to determine overall memory vs. physical read efficiency. Page Writes can give you an idea of overall physical write activity. There are a number of statistics, however, that pertain specifically to certain write activities like checkpoints, that can be examined to determine the amount of physical writes caused by distinct SQL Server processes.

Regarding performance, response times experienced by users are normally not impacted by write operations unless the writes are synchronous. These are typically BCPs, database recovery operations, and index creations.

### Database Bytes Read/Write Summary

The Database Bytes Read/Write Summary statistics represent the number of bytes read and written by SQL Server.

### Database I/O Detail

The Database I/O section of the Database I/O tab of the I/O Detail summarizes I/O activity for each database, letting you quickly spot the “hot” databases on your server. The table below describes the information available in the Database I/O Detail section:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Reads</td>
<td>The number of reads issued against the database.</td>
</tr>
<tr>
<td>Writes</td>
<td>The number of writes issued against the database.</td>
</tr>
<tr>
<td>Bytes Read</td>
<td>The total number of bytes read for the database.</td>
</tr>
<tr>
<td>Bytes Written</td>
<td>The total number of bytes written for the database.</td>
</tr>
<tr>
<td>I/O Stall</td>
<td>The total amount of time that processes have waited for I/O operations to complete, in milliseconds.</td>
</tr>
</tbody>
</table>
Consider moving databases with lots of I/O activity and wait time onto separate drives/devices.

**File Tab**

The File tab of I/O Detail includes the following sections:

- File Bytes Read/Write Summary
- File I/O Detail
- File Read/Write Summary

**File Read/Write Summary**

The Reads statistic represents that number of physical database page reads that are issued per second by SQL Server. The Writes statistic represents the number of physical database page writes issued by SQL Server. Writes take place during operations such as checkpoints, lazywriter writes, index creations, and BCP routines. Both statistics are collective in nature, meaning that they represent the total reads and writes across all databases that exist on the target SQL Server.

Page reads are to be expected, especially after initial server start up. This is because SQL Server must first satisfy requests for data and metadata by reading information from physical disk. Numerous page reads can also be expected if the physical server does not contain an adequate amount of memory to hold repetitively requested blocks of information. No hard and fast rules exist for how many page reads per second is too much. You can cross reference this statistic with the physical server disk statistics to see if physical page reads and accompanying physical disk I/O is approaching the server’s premium capacity levels. And because logical I/O is always many times faster than physical I/O, you should also evaluate the buffer cache hit ratio to determine overall memory vs. physical read efficiency. Page Writes can give you an idea of overall physical write activity. There are a number of statistics, however, that pertain specifically to certain write activities like checkpoints, that can be examined to determine the amount of physical writes caused by distinct SQL Server processes. Regarding performance, response times experienced by users are normally not impacted by write operations unless the writes are synchronous in nature. These are typically BCPs, database recovery operations, and index creations.

**File Bytes Read/Write Summary**

The File Bytes Read/Written statistics communicate the number of bytes read and written by SQL Server.
File I/O Detail

The File I/O Detail section of the File tab of the I/O Detail summarizes I/O activity for each database file, letting you quickly spot the “hot” databases and files on your server. The table below describes the information available in the File I/O Detail section:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>The database name.</td>
</tr>
<tr>
<td>File ID</td>
<td>The file identifier for the target file.</td>
</tr>
<tr>
<td>Logical Name</td>
<td>The name given the file by the DBA.</td>
</tr>
<tr>
<td>File Name</td>
<td>The physical file name of the file.</td>
</tr>
<tr>
<td>Timestamp</td>
<td>The internal time stamp of when the data was obtained.</td>
</tr>
<tr>
<td>Reads</td>
<td>The number of reads issued against the database file.</td>
</tr>
<tr>
<td>Writes</td>
<td>The number of writes issued against the database file.</td>
</tr>
<tr>
<td>Bytes Read</td>
<td>The total number of bytes read for the database file.</td>
</tr>
<tr>
<td>Bytes Written</td>
<td>The total number of bytes written for the database file.</td>
</tr>
<tr>
<td>I/O Stall</td>
<td>The total amount of time that processes have waited for I/O operations to complete, in milliseconds.</td>
</tr>
</tbody>
</table>

Metrics

Consider moving databases and/or files with lots of I/O activity and wait time onto separate drives/devices.
Space View (SQL Server Performance Analyst)

In addition to a Home page, the Space category of SQL Server Performance Analyst includes the following tabbed pages:

- File Groups Tab
- Files Tab
- Objects Tab
- Virtual Log Files Tab
- Server Space Tab

Home

The Home page of the Space category includes statistics in the following categories:

- Bottleneck Analysis Pane
- Disk Analysis Pane
- Space Analysis Pane
- SQL Analysis Pane

Space Analysis Pane

A SQL server contains many databases, some of which are devoted to system-level activities (the master and tempdb databases, for example) and others that hold user data. The Key Space Analysis section of the Space home page displays details about the space situation for each database in a SQL server, including their total, used, and free space. The percent used amount for each database is also shown. In addition, each database’s transaction log space is analyzed and presented.

Metrics

If a database or transaction log’s free space goes below the Performance Analyst recommended threshold, (and either the database or transaction log does not have its automatic growth property enabled or the files have reached their growth limit) then the DBA should take action to ensure that the database or transaction log does not run out of available free space.

Correction

If the percent used amount of a database is approaching problematic levels, there are three ways a DBA can rectify the situation:
1. The DBA can resize the current file(s) used by the database via an ALTER DATABASE … MODIFY FILE command.

2. The DBA can add a new file to the database via the ALTER DATABASE … ADD FILE command.

3. The DBA can modify the file(s) used by the database to automatically grow by using the ALTER DATABASE … MODIFY FILE … FILEGROWTH command. You should also ensure that the MAXSIZE setting of each file is set appropriately.

Of course, the DBA should also ensure that enough physical space exists on the server to accommodate additional database space. There are several things a DBA can do to ensure that a database’s log does not run out of available free space:

1. First, most transactional-oriented databases should have their logs assigned to separate physical drives other than the database. Reasons for doing this include:
   - It prevents competition for space between the log and the database itself.
   - It allows the log to be monitored for space more effectively.
   - It improves performance.

2. If the database is not critical in nature, you can set the truncate log on checkpoint option (trunc log on chkpt), which eliminates any non-active space in the log when a database checkpoint occurs.

3. Critical databases needing higher levels of recovery should have schedules established that regular perform transaction log dumps. Doing so ensures better recovery scenarios as well as a reduced risk of the transaction log running out of space.

4. If a critical transaction log becomes full, it might be impossible to use standard procedures to dump transactions and reclaim space. The dump operation will likely have to incorporate the no log or truncate only options.

5. If a transaction log continuously approaches dangerously low levels of free space, then the DBA should allow the underlying file(s) of the log to automatically grow to meet the demand. This can be accomplished by using the ALTER DATABASE … MODIFY FILE … FILEGROWTH command. You should also ensure that the MAXSIZE setting of each file is set appropriately.

The DBA should also be on the lookout for large load or data modification operations that do not make use of prudently timed commit points. A single, large transaction has the ability to overwhelm any transaction log since only non-active space in the transaction log is removed from log dumps or truncation operations.

**Bottleneck Analysis Pane**

When using bottleneck analysis to troubleshoot a database, a DBA cannot rely only on the information contained in the wait event views that SQL Server provides. For example, a database might attempt to allocate another segment of space and yet be
denied if no such free space exists on the server or if the underlying file has reached its growth limit. Such a failure will not be reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that a DBA cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain an accurate performance risk assessment. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system. The Performance Analyst Space home page displays space-related bottlenecks that might be threatening the overall performance of your system.

The following bottleneck indicators are used on the Performance Analyst Space home page to succinctly communicate the general overall space situation of the monitored database:

- Databases Without Auto-Grow
- Databases With Auto-Shrink
- Database Files Near Max Size
- Databases on Same Disk as Log
- Logs Without Auto-Grow
- Log Files Near Max Size

The following statistics, available on this pane, duplicate statistics available on the Bottleneck Analysis Pane of the Home View (SQL Server Performance Analyst) page:

- DB’s Low on Space
- Logs Low on Space

**Database Files Near Max Size**

A DBA can specify that one or more files of a SQL Server database can automatically grow by enabling the file’s auto-growth property. A DBA can also specify that the file not be permitted to grow beyond a certain limit, and once that limit is reached, the file and/or the database might be permanently out of space. The Database Files Near Max Size statistic provides a count of how many database files are near their maximum file size.
Databases on Same Disk as Log

To minimize I/O contention, a database should have its database files located on different physical disks than its log files. The Databases on Same Disk as Log statistic provides a count of how many databases have files that are on the same physical disk as their transaction log.

Databases Without Auto-Grow

In Microsoft SQL Server, a DBA has the ability to tell SQL Server to automatically grow a database in size when more space is required. This feature can save a critical transaction or other database request from failing due to a lack of free space in the database. It is recommended that critical databases have this feature enabled. The Databases Without Auto-Grow statistic provides a count of databases that do not have their automatic growth property enabled.
Static databases (those not expected to grow in size) will likely not need their auto-growth property enabled. Growing, dynamic databases should almost always be allowed to automatically grow when needed.

Correction: If any critical, dynamic database is found to not have its auto-growth feature enabled, then the DBA can modify the file(s) used by the database to automatically grow by using the ALTER DATABASE ... MODIFY FILE ... FILEGROWTH command. You should also ensure that the MAXSIZE setting of each file is set appropriately.

**Databases With Auto-Shrink**

A database can be set up to automatically shrink in size if SQL Server finds the database with an abundance of unused free space. Setting a database up so that this occurs can help reduce wasted storage on a database server. The Databases With Auto-Shrink statistic provides a count of databases that are allowed to automatically shrink in size.

Correction: If a DBA wants to configure a database to automatically shrink, they can issue a command similar to the following: `EXEC sp_dboption 'mydatabase','autoshrink',true`.

**Logs Without Auto-Grow**

In Microsoft SQL Server, a DBA has the ability to tell SQL Server to automatically grow a database or transaction log in size when more space is required. This feature can save a critical transaction or other database request from failing due to a lack of free space in the database or transaction log. It is recommended that critical databases and their transaction logs have this feature enabled.

The Logs Without Auto-Grow statistic provides a count of transaction logs that do not have their automatic growth property enabled.
Location  Microsoft SQL Server Performance Analyst Statistics > Space View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Static databases (those not expected to grow in size) will likely not need their transaction log’s auto-growth property enabled. Growing, dynamic databases should almost always have their transaction log be set to automatically grow when needed.

Correction  If any critical, dynamic database is found to not have their transaction log auto-growth feature enabled, then the DBA can modify the file(s) used by the database’s transaction log to automatically grow by using the ALTER DATABASE ... MODIFY FILE ... FILEGROWTH command. You should also ensure that the MAXSIZE setting for each file is set appropriately.

Log Files Near Max Size

A DBA can specify that one or more transaction log files of a SQL Server database can automatically grow by enabling the file’s auto-growth property. A DBA can also specify that the file not be permitted to grow beyond a certain limit, and once that limit is reached, the file and/or the transaction log might be permanently out of space. The Log Files Near Max Size statistic provides a count of how many transaction log files are near their maximum file size.

You should not see any positive indicator that any file has reached its growth limit. While it might be okay from the standpoint that a file cannot simply grow anymore (if the database transaction log has other files that can grow or that no more transactions are expected to occur within the database), the DBA should disable the auto-growth property of the file.

Location  Microsoft SQL Server Performance Analyst Statistics > Space View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Correction  If a file has reached its growth limit, a DBA can take a number of actions: Eliminate the growth limit for the file either by increasing the limit size or allowing to grow in an unlimited fashion. If the file is on a disk or file system that has no free space left, the DBA can add another file to the database’s transaction log to allow for space expansion and alter the problem file to have auto-growth property disabled.

SQL Analysis Pane

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end-user response times.

The SQL Analysis section of the Space home page shows a count of all SQL statements that have executed INSERT, UPDATE, DELETE, and TRUNCATE commands. Seeing these statistics should help you determine how much space-related SQL activity is occurring on your system.

The SQL Analysis section provides you with a quick overview of the percentage of Reads, Writes, CPU, and Elapsed Time the most expensive SQL statements tracked by Performance Analyst have used. Depending on the page you are on, you might just see
information regarding physical I/O activity or DML statements. For example, you might see that a SQL statement has caused 60% of all physical reads on the system, or that a procedure is responsible for 90% of all the CPU usage. To get information regarding the actual SQL text or stored procedure calls, drill down into the Top SQL details views.

**Note:** SQL Profiling is turned on by default in Performance Analyst so you can automatically collect SQL traffic. If you do not want to collect SQL execution information, use the options inside of Performance Analyst to disable SQL profiling.

**Metrics**

The statistics in this section can be used in many different ways. For example, large numbers of inserts could indicate a growing database and that a DBA should keep a watchful eye on free space. Heavy update numbers could mean trouble for objects containing many indexes (indexes typically undergo splits and fragmentation when large volumes of updates are thrown their way). Many deletes might signal potential wasted space problems.

**Disk Analysis Pane**

The Disk Analysis section of the Performance Analyst Space home page provides a summary of the total database and log space used per server disk drive, as well as a summary of free disk space for each server drive.

**Metrics**

If any database or transaction log file has been set up to automatically grow, the DBA should ensure there is enough server disk space to accommodate any new, additional requests for space.

**Correction**

If you see any drive that has reached zero free space (or is close), you might want to add new files, on other disks with abundant free space, to any databases or transaction logs so that no out-of-space errors result.

**File Groups Tab**

SQL Server manages physical storage space through files and file groups. The file groups tab displays detailed information regarding storage usage in each of the SQL Server file groups. The table below describes the information available in the File Groups Summary section of the File Groups tab:
### Information

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>File Group ID</td>
<td>The numeric ID of the file group.</td>
</tr>
<tr>
<td>File Group</td>
<td>The name of the file group.</td>
</tr>
<tr>
<td>Can Grow</td>
<td>This indicates if one of more of the files making up the file group is allowed to grow automatically.</td>
</tr>
<tr>
<td>File Count</td>
<td>The number of files that make up the file group.</td>
</tr>
<tr>
<td>Size (MB)</td>
<td>The total physical size of the file group.</td>
</tr>
<tr>
<td>Table Res</td>
<td>The amount of reserved space consumed by tables.</td>
</tr>
<tr>
<td>Index Res</td>
<td>The amount of reserved space consumed by indexes.</td>
</tr>
<tr>
<td>Free (MB)</td>
<td>The amount of free space for the file group.</td>
</tr>
<tr>
<td>Free Percent</td>
<td>The percentage of free space for the file group.</td>
</tr>
</tbody>
</table>

### Metrics

Unless server space is tight, it is normally wise practice to allow your files to automatically grow to meet demand for more incoming data. You should also physically separate your database and log files onto separate physical drives.

### Correction

To let your files automatically grow until out of space, set the file’s growth option in Embarcadero’s DBArtisan, or by using the ALTER DATABASE... MODIFY FILE command.

### Files Tab

SQL Server manages physical storage space through files and file groups. The Files tab displays detailed information regarding storage usage in each of the SQL Server files. The table below describes the information available in the Files Summary section of the Files tab:
**Information**

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Logical Name</td>
<td>The nickname given to the file by the DBA.</td>
</tr>
<tr>
<td>File Group</td>
<td>The name of the file group.</td>
</tr>
<tr>
<td>File Name</td>
<td>The name and location of the file.</td>
</tr>
<tr>
<td>Size (MB)</td>
<td>The total physical size of the file.</td>
</tr>
<tr>
<td>Can Grow</td>
<td>This indicates if the file can automatically grow in size.</td>
</tr>
<tr>
<td>Growth Amount</td>
<td>This indicates how much the file will grow in size.</td>
</tr>
<tr>
<td>Max File Size</td>
<td>This indicates the maximum file size that the file can grow.</td>
</tr>
</tbody>
</table>

**Metrics**

Unless server space is tight, it is normally wise practice to allow your files to automatically grow to meet demand for more incoming data. It is also smart to physically separate your database and log files onto separate physical drives.

**Correction**

To let your files automatically grow until out of space, set the file’s growth option in Embarcadero’s DBArtisan, or by using the ALTER DATABASE... MODIFY FILE command.

**Virtual Log Files Tab**

The Virtual Log Files tab of the Space Detail displays an internal structure of sorts for a each database’s log. The presented information is helpful when trying to shrink a database’s log because you can see how much of the log is active and exactly where the active portion resides. The table below describes the information available on the Virtual Log Files tab of the Space Detail:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>The name of database.</td>
</tr>
<tr>
<td>File Name</td>
<td>The name of the log file.</td>
</tr>
<tr>
<td>Status</td>
<td>This indicates if this portion of the log is active or inactive (not being used).</td>
</tr>
<tr>
<td>Size</td>
<td>The size of this portion of the log in MBs.</td>
</tr>
</tbody>
</table>

**Objects Tab**

The Objects tab of the Space/Databases Detail includes the following sections:

- Database Object Detail
Database Object Summary

Tables and indexes consume the storage in all databases. The Database Object Summary grid displays summary information regarding table and index storage for all databases. The table below describes the information available in the Database Object Summary section of the Objects tab of the Space Detail:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Table Count</td>
<td>The count of all tables in the database.</td>
</tr>
<tr>
<td>Index Count</td>
<td>The count of all indexes in the database.</td>
</tr>
<tr>
<td>Table Reserved (MB)</td>
<td>The amount of space (in MB) reserved by tables.</td>
</tr>
<tr>
<td>Index Reserved (MB)</td>
<td>The amount of space (in MB) reserved by indexes.</td>
</tr>
</tbody>
</table>

Metrics Negative numbers viewed for index space information can be caused by inaccuracies contained in the SQL Server data dictionary. Frequently, running a DBCC UPDATEUSAGE command against the database resolves the problem. However, there are bugs in SQL Server that sometimes caused erroneous numbers to the reported for the reserved space amounts used by tables and indexes.

Database Object Detail

Tables and indexes consume the storage in all databases. The Database Object Detail grid displays object space details for the database selected in the Database Object Summary grid. The table below describes the information available in the Database Object Detail section of the Objects tab of the Space Detail:
Information Description

Object Owner The owner of the object.
Object Name The name of the object.
Clustered Indicates if the index is clustered.
File Group The file group where the object resides.
Reserved (KB) The amount of space reserved by the object in kilobytes.
Used (KB) The amount of space used by the object in kilobytes.
Free (KB) The amount of free space used by the object in kilobytes.
Percent Used The percentage of space used by the object.

Location Microsoft SQL Server Performance Analyst Statistics > Space View (SQL Server Performance Analyst) > Objects TabMicrosoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Objects Tab

Metrics Negative numbers viewed for index space information can be caused by inaccuracies contained in the SQL Server data dictionary. Frequently, running a DBCC UPDATEUSAGE command against the database resolves the problem. However, there are bugs in SQL Server that sometimes caused erroneous numbers to the reported for the reserved space amounts used by tables and indexes.

Server Space Tab

The Server Space tab of the Space Detail displays the amounts of space used by SQL Server per physical drive and by database per physical drive. The first section displays summary information and the second section contains space information per database.

The table below describes the information available in the Disk Summary By Space section on the Server Space tab of the Space Detail:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Data (MB)</td>
<td>The amount of reserved database space on the drive.</td>
</tr>
<tr>
<td>SQL Log (MB)</td>
<td>The amount of reserved log space on the drive.</td>
</tr>
<tr>
<td>Free</td>
<td>The total amount of free space that remains on the drive.</td>
</tr>
</tbody>
</table>

The table below describes the information available in the Disk Summary By Database section on the Server Space tab of the Space Detail:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disk Drive</td>
<td>The physical drive letter.</td>
</tr>
<tr>
<td>Database</td>
<td>The database name.</td>
</tr>
<tr>
<td>SQL Data (MB)</td>
<td>The amount of reserved database space on the drive.</td>
</tr>
<tr>
<td>SQL Log (MB)</td>
<td>The amount of reserved log space on the drive.</td>
</tr>
</tbody>
</table>

**Metrics**

If you allow your database and/or log files to automatically grow, and you see little or no free space left on their physical drives, an option is to add new files to the database or log on different drives to avoid any out of space errors. It is also smart to physically separate your database and log files onto separate physical drives.

**Correction**

If you need to add new files to your databases or logs, you can do so easily by using the ALTER DATABASE... ADD FILE and ALTER DATABASE... ADD LOG FILE commands.
Users View (SQL Server Performance Analyst)

In addition to a Home page, the Users category of SQL Server Performance Analyst includes the following tabbed pages:

- Locks Tab
- Session Waits Tab
- System Waits Tab
- Top Sessions Tab

Home

The Home page of the Users Performance Analyst statistics includes the following categories:

- Bottleneck Analysis Pane
- Key User Analysis Pane
- Login Analysis
- SQL Analysis Pane
- Workload Analysis Pane

Key User Analysis Pane

User database activity can be examined using key performance statistics and wait/bottleneck-based analysis.

The following key statistics are used on the Performance Analyst Users home page to succinctly communicate the general session-based activity levels of the monitored database:
**Active Processes**  The Active Processes statistic represents the total number of active and open threads reported on the server. This number displays the number of processes actively performing work.

**Active Transactions**  The active transactions statistic represents a count of the number of in-process transactions for SQL Server.

**Inactive Processes**  This metric represents the total number of threads logged on to the server that are idle at the current time.

**System Processes**  The System Processes statistic represents the total number of threads logged on to the server that are SQL Server internal processes.

**Transaction/Sec**  The transaction/sec statistic refers to the number of database transactions processed per second by SQL Server.

**T-SQL Batches**  The T-SQL batches statistic refers to the number of transact SQL batches processed by SQL Server.

**Bottleneck Analysis Pane**

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. And this is where wait-based or bottleneck analysis comes into play. DBAs use this form of performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps a DBA track where a database has been spending its time. If lock contention or heavy table scan activity has been dragging down database performance, a DBA can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, the DBA can drill down and oftentimes discover a fair amount of detail about which sessions and objects are causing the problem. The Performance Analyst Home page identifies the top system and session waits that might be currently a cause of lessened performance.

When using bottleneck analysis, you cannot rely only on the information contained in the wait events that SQL Server provides. For example, a database might be suspect or offline. Such a failure will not be reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that a DBA cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain an accurate performance risk assessment. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system. The Performance Analyst Home page displays space-related bottlenecks as well as other sources of contention/bottlenecks that might be dragging down the overall performance of your system.
The following bottleneck indicators are used on the Performance Analyst Users home page to succinctly communicate the general overall performance level of the monitored database:

- Current Blocked Processes
- Failed Auto-Param Attempts
- Lock Timeouts
- Lock Waits
- Lock Wait Time
- Scan Point Revalidations
- SQL Re-Compilations
- Top Bottlenecked User Processes

The following statistic, available on this pane, duplicates a statistic appearing on the Bottleneck Analysis Pane of the Home View (SQL Server Performance Analyst) page:

- Table Lock Escalations

**Current Blocked Processes**

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Blocks are most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency. Unless a process times out via an application timeout mechanism, or the process has specified a timeout period via the SET LOCK_TIMEOUT command, a process waiting for a lock will wait indefinitely.
You should immediately investigate any indicator above zero, before the situation has a chance to mushroom.

Correction Once discovered, a blocking lock situation can normally be quickly remedied - the DBA issues a KILL against the offending process, which eliminates the user's stranglehold on the objects they were accessing. Other user processes then almost always complete in an instant. Discovering the blocked lock situation is made easier by using tools like Performance Analyst, but preventing the blocking lock situation in the first place is where it gets tricky. The DBA can drill down into user detail and view all current blocking locks to see exactly which sessions are holding the currently restrictive locks. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. By default, all processes wait indefinitely for locks in SQL Server. You can change this behavior by using the SET LOCK_TIMEOUT command, which limits the number of seconds that a process will wait for a lock before timing out.

Failed Auto-Param Attempts

Auto-parameterization occurs when an instance of SQL Server attempts to reuse a cached plan for a previously executed query that is similar to, but not the same as, the current query. The Failed Auto-Param Attempts statistic shows the number of failed auto-parameterization attempts per second.

Correction You can increase the ability of the relational engine to match complex SQL statements to existing, unused execution plans, by explicitly specify the parameters using either sp_executesql or parameter markers in your T-SQL code. Doing so helps lower this number.

Lock Timeouts

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Blocks are most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency. Unless a process times out via an application timeout
mechanism, or the process has specified a timeout period via the SET LOCK_TIMEOUT command, a process waiting for a lock will wait indefinitely. The lock timeouts represent the number of locks that have timed out due to the issuing of the aforementioned command.

**Location** Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics** Any indicator above zero might indicate the presence of lock contention on the server.

**Correction** Once discovered, a blocking lock situation can be quickly remedied - the DBA issues a KILL against the offending process, eliminating the user’s stranglehold on the objects they were accessing. Other user processes then almost always complete in an instant. Discovering the blocked lock situation is made easier by using tools like Performance Analyst, but preventing the blocking lock situation in the first place is more difficult. You can drill down into user detail and view all current blocking locks to see exactly which sessions are holding the currently restrictive locks. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. By default, all processes wait indefinitely for locks in SQL Server. You can change this behavior by using the SET LOCK_TIMEOUT command, which limits the number of seconds that a process will wait for a lock before timing out.

### Lock Waits

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Blocks are most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency. Unless a process times out via a timeout mechanism, or the process has specified a timeout period via the SET LOCK_TIMEOUT command, a process waiting for a lock will wait indefinitely. The Lock Waits statistic represents the number of lock requests that required a process to wait.
Users View (SQL Server Performance Analyst)

Location  Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Any indicator above zero might indicate the presence of lock contention on the server.

Correction Once discovered, a blocking lock situation can be quickly remedied - the DBA issues a KILL against the offending process, which eliminates the user’s stranglehold on the objects they were accessing. Other user processes then almost always complete in an instant. Discovering the blocked lock situation is made easier by tools like Performance Analyst, but preventing the blocking lock situation in the first place is more difficult. The DBA can drill down into user detail and view all current blocking locks to see exactly which sessions are holding the currently restrictive locks. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. By default, all processes wait indefinitely for locks in SQL Server. You can change this behavior by using the SET LOCK_TIMEOUT command, which limits the number of seconds that a process will wait for a lock before timing out.

Lock Wait Time

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Blocks are most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency. Unless a process times out via an application timeout mechanism, or the process has specified a timeout period via the SET LOCK_TIMEOUT command, a process waiting for a lock will wait indefinitely. The lock wait time statistic represents the wait time (in milliseconds) that processes have had to wait to obtain a lock request.
Correction Once discovered, a blocking lock situation can normally be quickly remedied - the DBA issues a KILL against the offending process, which eliminates the user’s stranglehold on the objects they were accessing. Other user processes then nearly always complete in an instant. Discovering the blocked lock situation is made easier by using tools like Performance Analyst, but preventing the blocking lock situation in the first place is where it gets tricky. The DBA can drill down into user detail and view all current blocking locks to see exactly which sessions are holding the currently restrictive locks. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. By default, all processes wait indefinitely for locks in SQL Server. You can change this behavior by using the SET LOCK_TIMEOUT command, which limits the number of seconds that a process will wait for a lock before timing out.

**Scan Point Revalidations**

The Scan Point Revalidations statistic represents the number of times per second that the scan point had to be revalidated to continue the scan.

**SQL Re-Compilations**

The SQL re-compilations statistic represents the total number of recompiles triggered per second in a SQL Server instance. Recompiles occur when SQL Server determines that the currently defined execution plan for an executing stored procedure might no longer be the best possible plan. SQL Server pauses the query execution and recompiles the stored procedure.
Recompiles slow down the process that is executing the procedure and increase the load on the CPU. By extension, the more recompiles that are occurring on your system, the more overall load increases, resulting in poor performance. In general, you want to keep the number of recompiles low. The most common reasons SQL Server would issue a recompile are: Running sp_recompile against any table referenced in the stored procedure, significant data changes in a referenced table, schema changes to referenced objects, the use of the WITH RECOMPILE clause in the CREATE PROCEDURE or EXECUTE statement, and a plan no longer available in the system cache.

Correction
Try to practice coding standards that eliminate the most frequent causes detailed above. Also, try to: Use temporary tables only in the stored procedure that created them. Minimize creating temporary tables in control block structures. Use the KEEP PLAN option on references to static temporary tables. Issue the CREATE TABLE statement before any other references to the created table. Minimize the use of temporary tables.

Top Bottlenecked User Processes
When viewing wait statistics, there are several levels of detail that a DBA can drill down into. The first level is the system view, which provides a global, cumulative snapshot of all the waits that have occurred on a system. The second level is the session view, which shows details on what events connected sessions are experiencing. Viewing these numbers can help a DBA determine which session-related wait events have caused the most commotion in a database thus far. The Top Bottlenecked User Processes display identifies the processes with the most current wait time along with the event causing their current wait.

SQL Analysis Pane
A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured server down in terms of end-user response times.

Before you can identify problem SQL in your database, you have to ask the question - “What is bad SQL?” What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every SQL Server professional’s satisfaction. The table below lists some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:
Users View (SQL Server Performance Analyst)

### Criteria

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reads (Physical)</td>
<td>This is often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user’s request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at a statements’ logical I/O as well.</td>
</tr>
<tr>
<td>Writes</td>
<td>These can be caused by DML activity (INSERTs, etc.), but writes can also be indicative of heavy disk sort activity.</td>
</tr>
<tr>
<td>CPU Time</td>
<td>This is how much CPU time the query took to parse, execute, and fetch the data needed to satisfy the query.</td>
</tr>
<tr>
<td>Elapsed Time</td>
<td>This is how much time the query took to parse, execute, and fetch the data needed to satisfy the query. It should not include the network time needed to make the round trip from the requesting client workstation to the database server.</td>
</tr>
</tbody>
</table>

There are other criteria that you can examine like sort activity or access plan statistics (that show items like Cartesian joins and the like), but more often than not, these measures are reflected in the criteria listed above.

The SQL Analysis section provides you with a quick overview of the percentage of Reads, Writes, CPU, and Elapsed Time the most expensive SQL statements tracked by Performance Analyst have used. Depending on the page you are on, you might just see information regarding physical I/O activity or DML statements. For example, you might see that a SQL statement has caused 60% of all physical reads on the system, or that a procedure is responsible for 90% of all the CPU usage. To get information regarding the actual SQL text or stored procedure calls, drill down into the Top SQL details views.

**Note:** SQL Profiling is turned on by default in Performance Analyst so you can automatically collect SQL traffic. If you do not want to collect SQL execution information, use the options inside of Performance Analyst to disable SQL profiling.

### Metrics

When you begin to look for inefficient SQL in a database, there are two primary questions you should answer:

- What has been the worst SQL that has historically been run in my database?
- What is the worst SQL that is running right now in my database?

When correcting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It might be that the query is in an inefficient Transaction SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.
There is the possibility that the SQL statement just is not tuned well. To determine that, you can drill down further into the Performance Analyst Top SQL view and begin working with the query through EXPLAIN plan analysis and other techniques inside Embarcadero’s DBArtisan.

Login Analysis

The Login Analysis section displays the number of successful login and logout operations.

Location Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Home > SQL Analysis Pane

Workload Analysis Pane

When the database population as a whole experiences a system slowdown, it is not uncommon to find one or two users who are responsible for bringing the system to its knees. In the best of worlds, users will have a pretty evenly divided amount of memory usage, disk I/O, CPU utilization, and parse activity. Unfortunately, this usually is not the case, and many times you will find users submitting large batch jobs during peak OLTP activity, or sessions that are firing off untuned queries on a critical system.

If you are seeing a slowdown in your database, and cannot seem to find a root cause, one thing to examine is the resource consumption of the leading sessions on a system. Oftentimes you will find one or a handful of users making things miserable for everyone else. They accomplish this by overwhelming the I/O capabilities of SQL Server (through untuned queries or runaway batch jobs) or hammering the CPU or memory structures of the database and server.

Performance Analyst makes it easy to pinpoint the top sessions by showing the leading processes at the physical I/O, memory, CPU, and transaction submission usage levels.

Metrics

If any one session appears to be using more than 50% of a total resource (CPU, memory, etc.), then you should drill down into the session to find out what they are currently executing.

Top Sessions Tab

The Top Sessions tab of the Users Detail includes the following processes:

- Top CPU Process
- Top I/O Process
- Top Memory Process
- Top Sessions
Top I/O Process

The Top I/O Process statistic identifies the SQL Server process that currently has caused the most I/O usage on the database.

Location: Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Top Memory Process

The Top Memory Process statistic identifies the SQL Server process that currently is using the highest percentage of memory in the database.

Location: Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Top CPU Process

The Top CPU Process statistic identifies the SQL Server process that currently has the highest percentage of CPU usage in the database.

Location: Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Top Sessions

When a system experiences heavy activity, sometimes you will find that all the user connections are contributing somewhat equally to the overall load. More often than not, however, one or two user connections are causing most of the activity. It might be that a large batch load or other typical process is running that is perfectly okay for your system. Or it might be a runaway process or other rogue connection that needs to be tracked down and possibly eliminated.

Top Sessions displays information regarding all key statistics for all current sessions on a SQL Server. The table below describes the information available in the Top Sessions section on the Top Sessions tab of the Users Detail:
Users View (SQL Server Performance Analyst)

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPID</td>
<td>The unique identifier for the process.</td>
</tr>
<tr>
<td>Login</td>
<td>The login name for the process.</td>
</tr>
<tr>
<td>Windows User</td>
<td>The operating system name of the process.</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database the process is working in.</td>
</tr>
<tr>
<td>Status</td>
<td>The current status of the process.</td>
</tr>
<tr>
<td>Program</td>
<td>This identifies the program being run by the process.</td>
</tr>
<tr>
<td>Memory</td>
<td>The number of pages in the procedure/SQL cache allocated to the process.</td>
</tr>
<tr>
<td>CPU</td>
<td>The cumulative CPU time for the process.</td>
</tr>
<tr>
<td>Physical I/O</td>
<td>The cumulative total of all physical reads and writes for the process.</td>
</tr>
<tr>
<td>Blocked</td>
<td>This indicates if the process is blocked by another process.</td>
</tr>
<tr>
<td>Host</td>
<td>This identifies the workstation of the process.</td>
</tr>
<tr>
<td>Open Transaction</td>
<td>This indicates if the process has an open transaction.</td>
</tr>
<tr>
<td>Command</td>
<td>The command being currently issued by the process.</td>
</tr>
<tr>
<td>Login Time</td>
<td>This identifies when the process logged into SQL Server.</td>
</tr>
<tr>
<td>Last Batch</td>
<td>This indicates the date/time the process executed a remote stored procedure or issued an EXEC command.</td>
</tr>
<tr>
<td>Host Process</td>
<td>The process identifier on the SQL Server machine.</td>
</tr>
<tr>
<td>Net Address</td>
<td>The network address of the process.</td>
</tr>
</tbody>
</table>

Current SQL

This view shows a snippet of the SQL associated with the user in question.

System Waits Tab

The System Waits tab of the Users Detail includes the following sections:
System Waits

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The System Waits section identifies the waits that have occurred on SQL Server. The System Waits section identifies the waits that have occurred on SQL Server. The table below describes the information available in the System Waits section on the System Waits tab of the Users Detail:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wait Type</td>
<td>The actual wait event name.</td>
</tr>
<tr>
<td>Requests</td>
<td>The number of waits.</td>
</tr>
<tr>
<td>Percent of Total</td>
<td>The percentage of the occurrences of this wait to all wait requests.</td>
</tr>
<tr>
<td>Time Waited</td>
<td>The number of seconds SQL Server spent waiting for this wait.</td>
</tr>
<tr>
<td>Percent Time Waited</td>
<td>The percentage of time SQL Server spent waiting on this wait.</td>
</tr>
<tr>
<td>Signal Wait Time</td>
<td>The signal wait time for the wait.</td>
</tr>
<tr>
<td>Percent Signal Wait</td>
<td>The percentage of signal wait time SQL Server spent waiting on this wait.</td>
</tr>
</tbody>
</table>

Location: Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > System Waits Tab

Metrics: Wait events can be hard to interpret at times. If you see a particular event that has caused a lot of wait time, you can review the information in this link (Microsoft Knowledge Base Article - 244455) to help understand the cause and potential remedy: http://support.microsoft.com/default.aspx?scid=kb;en-us;Q244455

Correction

The table below describes some possible solutions to some of the most common wait events:
<table>
<thead>
<tr>
<th>Wait Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURSOR</td>
<td>This indicates SQL is waiting to sync up with asynchronous cursors and can point to the excessive use of cursors.</td>
</tr>
<tr>
<td>CMEMTHREAD</td>
<td>This indicates waits for memory to be freed up for use.</td>
</tr>
<tr>
<td>CXPACKET</td>
<td>This relates to SQL Server parallelism. Oftentimes the cost of SQL Server using parallelism for a query is high, with the end result being these types of waits. If high, you can adjust SQL Server and turn parallelism off for the server or for just low cost queries.</td>
</tr>
<tr>
<td>EXCHANGE</td>
<td>Related to CXPACKET. See information above.</td>
</tr>
<tr>
<td>IO_COMPLETION</td>
<td>This means certain I/O related actions are being delayed. Bulk insert operations, growth of database or log files, high physical I/O SQL, page splitting, and server paging are potential causes. You can check Performance Analyst’s SQL Analysis section to ferret out heavy I/O SQL and the Database and File I/O Detail pages to examine disk and database hot spots with respect to I/O. The I/O Stall column is especially useful in determining which files are experiencing the most delays.</td>
</tr>
<tr>
<td>LOGMGR</td>
<td>This refers to waits for the Log Writer to start writing a transaction. High waits here might warrant transfer transaction logs to faster devices or breaking up long running DML transactions.</td>
</tr>
<tr>
<td>OLEDB</td>
<td>This indicates waits for an OLE DB operation to act on its requests. Slow connection speeds or very high transaction rates can cause these.</td>
</tr>
<tr>
<td>PAGELATCH</td>
<td>Related to IO_COMPLETION. See information above.</td>

<tr>
<td>PAGEIOLATCH</td>
<td>Related to IO_COMPLETION. See information above.</td>
</tr>
<tr>
<td>PAGESUPP</td>
<td>Related to CXPACKET. See information above.</td>
</tr>
<tr>
<td>PSS_CHILD</td>
<td>This is SQL waiting for a child thread within an asynchronous cursor and can point to the excessive use of cursors.</td>
</tr>
<tr>
<td>TEMPOBJ</td>
<td>This wait occurs when temp tables and the like are dropped.</td>
</tr>
<tr>
<td>WAITFOR</td>
<td>Waits caused by the WAITFOR T-SQL command. Not a cause for concern.</td>
</tr>
<tr>
<td>WRITELOG</td>
<td>Related to LOGMGR. Refers to waits for writes to disk of transactions. See information above.</td>
</tr>
<tr>
<td>XACTLOCKINFO</td>
<td>Involves the release of escalation of locks during bulk operations.</td>
</tr>
</tbody>
</table>

**Wait Percent by Total Waits**

When SQL Server is running, every connected process is either busy doing work or waiting for work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The Wait Percent by Total Waits section graphically depicts the top waits as a percentage of all waits.
Correction: Wait events can be hard to interpret at times. If you see a particular event that has caused a lot of wait time, you can review the information in this link (Microsoft Knowledge Base Article - 244455) to help understand the cause and potential remedy: http://support.microsoft.com/default.aspx?scid=kb;en-us;Q244455

Wait Percent by Time Waited

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The Wait Percent by Time Waited section graphically depicts the top waits by their percentage of time waited to total time waited.

Session Waits Tab

The Session Waits tab of the Users Detail includes the following sections:

- **Session Wait Percent by Time Waited**
- **Session Wait Percent by Wait Type**
- **Session Waits**

Session Waits

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The Session Waits section shows processes that are currently waiting on SQL Server. The table below describes the information available in the Session Waits section on the Session Waits tab of the Users Detail:
Users View (SQL Server Performance Analyst)

**Session Wait Percent by Wait Type**

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The Session Wait Percent by Wait Type section graphically depicts the top waits by wait type.
Correction Wait events can be hard to interpret at times. If you see a particular event that has caused a lot of wait time, you can review the information in this link (Microsoft Knowledge Base Article - 244455) to help understand the cause and potential remedy: http://support.microsoft.com/default.aspx?scid=kb;en-us;Q244455

Session Wait Percent by Time Waited

When SQL Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The Session Wait Percent by Time Waited section graphically depicts the top session waits by their percentage of time waited to total time waited.

Locks Tab

The Locks tab of the Users Detail includes the following sections:

- **Locks**
- **Locks by Lock Type**
- **Locks by Database**

Locks

To modify database information or structures, a user session must obtain a lock on the object to perform its task. In addition to user locks, SQL Server itself issues lock requests to carry out its internal duties. The Locks section gives information the locks currently on the system and also indicates if any blocking situations are occurring. The table below describes the information available in the Locks section:
<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPID</td>
<td>The process id of the process holding the lock.</td>
</tr>
<tr>
<td>Login</td>
<td>The login name of the process.</td>
</tr>
<tr>
<td>Windows User</td>
<td>The operating system name of the process.</td>
</tr>
<tr>
<td>Database</td>
<td>The database in which the process is running.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table involved in a lock. This will be NULL for non-table locks or table locks that take place in the tempdb database.</td>
</tr>
<tr>
<td>Index ID</td>
<td>The index ID involved in the lock.</td>
</tr>
<tr>
<td>Lock Type</td>
<td>The type of the lock (database, table, row id, etc.)</td>
</tr>
<tr>
<td>Lock Mode</td>
<td>The lock's mode (shared, exclusive, etc.)</td>
</tr>
<tr>
<td>Lock Status</td>
<td>The lock's status (waiting or granted).</td>
</tr>
<tr>
<td>Lock Owner Type</td>
<td>Whether the lock came from a regular session or a transaction.</td>
</tr>
<tr>
<td>User Program</td>
<td>The executable the process is using against the server.</td>
</tr>
<tr>
<td>Blocking SPID</td>
<td>If zero, the process is not being blocked. If non-zero, this column represents the process ID of the process blocking the requested lock.</td>
</tr>
<tr>
<td>Wait Time</td>
<td>The current amount of wait time for the process, in milliseconds.</td>
</tr>
<tr>
<td>SPID Status</td>
<td>Indicates if the process is actively performing work, is idle, blocked by another process, etc.</td>
</tr>
<tr>
<td>SPID Command</td>
<td>The command the process is currently issuing.</td>
</tr>
<tr>
<td>NT Domain</td>
<td>The name of Windows 2000/NT domain.</td>
</tr>
</tbody>
</table>
Users View (SQL Server Performance Analyst)

Location  Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Locks Tab

Metrics  Once discovered, a blocking lock situation can normally be quickly remedied - the DBA issues a KILL against the offending process, which eliminates the stranglehold on the objects the user was accessing. Other user processes then almost always complete in an instant. Discovering the blocked lock situation is made easier by using tools like Embarcadero Performance Analyst, but preventing the blocking lock situation in the first place is tricky. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. By default, all processes wait indefinitely for locks in SQL Server. You can change this behavior by using the SET LOCK_TIMEOUT command, which limits the number of seconds that a process waits for a lock before timing out.

Locks by Lock Type

To modify database information or structures, a user session must obtain a lock on the object to perform its task. In addition to user locks, SQL Server itself issues lock requests to carry out its internal duties. The Locks by Lock Type section of the Users Detail provides a graphical percentage breakdown of the different locks types being issued across all databases.

Location  Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Locks Tab

Locks by Database

The Locks by Database section of the Lock tab provides a graphical representation of the percentage breakdown of locks by database.

Location  Microsoft SQL Server Performance Analyst Statistics > Users View (DBArtisan - SQL Server Performance Analyst) > Locks Tab
Database View (SQL Server Performance Analyst)

In addition to a Home page, the Database category of SQL Server Performance Analyst includes the following tabbed pages:

- Backups Tab
- Configuration Tab
- Error Log Tab
- Overview Tab
- Replication Tab
- SQL Agent Tab
- Objects Tab

Home

The Home page of the Database Performance Analyst page includes the following categories:

- Bottleneck Analysis Pane
- Database Analysis Pane
- SQL Analysis Pane
- Workload Analysis Pane

Database Analysis Pane

SQL Server is broken up into many different databases, all of which have their own levels of activity. The Database Analysis section displays a summary of activities that have occurred within each database. The table below describes the information available in the Database Analysis section:
### Information

<table>
<thead>
<tr>
<th>Database Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The name of the database.</td>
<td></td>
</tr>
</tbody>
</table>

| DBCC Logical Scans | The number of DBCC scans that have occurred within the database. |

| Transactions | The number of transactions that have occurred within the database. |

| Active Transactions | The number of transactions currently running in the database. |

| Bulk Copy Rows | The number of rows inserted per second into the database via BCP operations. |

| Bulk Copy Throughput | The amount of data bulk (KB) copied into the database per second. |

| Log Cache Reads | The number of reads per second that have gone through the log manager cache. |

| Log Flashes | The number of transaction log flushes per second. A log flush occurs when SQL Server writes all changes from the database’s log cache out to the database’s log files on disk. |

| Log Growths | The number of times the transaction log has grown in size. |

| Log Shrinks | The number of times the transaction log has reduced itself in size. |

### Bottleneck Analysis Pane

When using bottleneck analysis to troubleshoot a database, a DBA cannot rely only on the information contained in the wait event views that SQL Server provides. For example, a critical database might be offline or be marked suspect. Such a failure will not be reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that a DBA cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain an accurate performance risk assessment. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system. The Performance Analyst Database home page displays database-related bottlenecks that might be dragging down the overall performance of your system.

The following bottleneck indicators are used on the Performance Analyst Database home page to communicate the general overall conditions of databases on the monitored server:

- [Databases Requiring Backup](#)
- [Databases Without Auto-Create Stats](#)
- [Databases Without Auto-Update Stats](#)
DATABASEVIEW (SQL SERVER PERFORMANCE ANALYST)

- Extents Allocated
- Freespace Scans
- Page Splits

The following statistics, available on this page, duplicate statistics available on the Bottleneck Analysis Pane of the Home View (SQL Server Performance Analyst) page:

- Suspect Databases
- Offline Databases

### Databases Requiring Backup

This metric represents the number of databases in SQL Server that have not been backed up for more than seven days. This statistic excludes the pubs, tempdb, Northwind, msdb, and model databases.

**Location**

Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**

To ensure proper protection for most databases, it is recommended that even the most static databases be backed up at least once a week. You should frequently backup critical, dynamic databases and include transaction log backups to enable point-in-time recovery ability.

**Correction**

Any critical databases found with obsolete or no backups should immediately be backed up. Moreover, to ensure proper data protection for each database, you should institute a planned backup schedule. The timing and repetition of the backups depend on the critical recovery needs of each database.

### Databases Without Auto-Create Stats

The Databases Without Auto-Create Stats statistic represents the total number of databases defined on SQL Server that do not have the AUTO_CREATE_STATISTICS option enabled.
When the AUTO_CREATE_STATISTICS option is enabled, statistics are automatically created on columns used in a SQL query predicate. Keeping object statistics fresh in the SQL Server data dictionary improves query performance because the optimizer can better determine how to evaluate a query and return the requested data. If the statistics are not used, SQL Server should automatically delete them.

Correction
If possible, a DBA should keep their databases in AUTO_CREATE_STATISTICS mode. If a database is found without this option set, you can easily change it by using the command: EXEC sp_dboption '<database name>', 'auto create statistics', true

Databases Without Auto-Update Stats

The Databases Without Auto-Update Statistics statistic represents the total number of databases defined on SQL Server that do not have the AUTO_UPDATE_STATISTICS option enabled.

Correction
If possible, a DBA should keep databases in AUTO_UPDATE_STATISTICS mode. If a database is found without this option set, you can easily change its auto-update statistics to true by using the command: EXEC sp_dboption '(database name)',

Extents Allocated

SQL Server groups eight 8KB pages together to form an extent of space (64KB). Space is allocated to database objects (tables, indexes) in the form of extents. The Extents Allocated statistic provides a count of the number of extents allocated to tables and indexes.

Correction
None. However, be aware that excessive counts of allocated extents might signal a large load job occurring in the database.

Freespace Scans

The Freespace Scans statistic provides a count of the number of scans SQL Server initiated to search for free space that will accommodate requests to insert new data rows.
Page Splits

When data is added or modified for a table that has indexes, the indexes must be updated as well. As index pages fill up, free space needed to keep index keys in their proper order can oftentimes run very low. If an index update needs to be made to a page, and no free space exists on that page, SQL Server will perform a page split where it moves approximately half the rows on a page to a new page. The Page Splits statistic provides a count of how many page splits are occurring in SQL Server.

Correction
To avoid page splits, you can look into tuning the FILLFACTOR property of an index, which controls the percentage of the index page that is filled during creation. The default, 100, tells SQL Server to completely fill each page, whereas lower numbers tell SQL Server to leave room for additional index rows or updates to existing rows.

SQL Analysis Pane

Certain databases on a SQL Server will experience more SQL activity than others. The SQL Analysis section displays a count of all statement executions for each database.

The SQL Analysis section provides you with a quick overview of the percentage of Reads, Writes, CPU, and Elapsed Time the most expensive SQL statements tracked by Performance Analyst have used. Depending on the page you are on, you might just see information regarding physical I/O activity or DML statements. For example, you might see that a SQL statement has caused 60% of all physical reads on the system, or that a procedure is responsible for 90% of all the CPU usage. To get information regarding the actual SQL text or stored procedure calls, drill down into the Top SQL details views.

Note: SQL Profiling is turned on by default in Performance Analyst so you can automatically collect SQL traffic. If you do not want to collect SQL execution information, use the options inside of Performance Analyst to disable SQL profiling.

Error Log Analysis pane

SQL Server records various system events in its system or error log. The majority of messages placed into the log are informational in nature, however since some contain critical messages, you should immediately review them. This section indicates the number of actual error messages in the most recent error log so you know if there are potential events that require your attention.
Note: Similar information is also available on the Bottleneck Analysis Pane of the Home View (SQL Server Performance Analyst) page.

Metrics

You should investigate any positive values for errors.

Correction

If non-zero values are found for this statistic, you should drill down into the current error log and examine the detail found that accompanies each error issued by SQL Server.

Workload Analysis Pane

SQL Server is broken up into many different databases, all of which have their own levels of activity. The Workload Analysis section displays a summary of resource consumption across all databases. The table below describes the information available in the Workload Analysis section:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Connections</td>
<td>The number of processes that are connected to the database.</td>
</tr>
<tr>
<td>Blocked Users</td>
<td>The number of processes in the database experiencing blocks from lock activity.</td>
</tr>
<tr>
<td>Total Memory</td>
<td>The total number of memory pages in use by processes for each database.</td>
</tr>
<tr>
<td>Total I/O</td>
<td>The total amount of physical I/O being experienced by each database.</td>
</tr>
<tr>
<td>Total CPU</td>
<td>The total amount of cumulative CPU for all processes connected to the database.</td>
</tr>
<tr>
<td>Total Wait Time</td>
<td>The total wait time (in milliseconds) that all processes connected to the database have experienced.</td>
</tr>
<tr>
<td>DBCC Running Count</td>
<td>This indicates if any DBCC operations are currently running against the database.</td>
</tr>
<tr>
<td>BCP Running</td>
<td>This indicates if any BCP operations are currently running against the database.</td>
</tr>
<tr>
<td>Backup Restore Running</td>
<td>This indicates if any backup or restore operations are currently running against the database.</td>
</tr>
</tbody>
</table>

Overview Tab

The Overview tab of the Database Detail includes the following sections:

- Database Object Analysis
Database View (SQL Server Performance Analyst)

- Database Size Analysis
- Database Summary
- Database User Analysis

**Database Size Analysis**

The Database Size Analysis chart displays each database in terms of its total percentage of size to the total size of all databases on the SQL Server.

Location: [Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane](#)

**Database Object Analysis**

The Database Object Analysis chart displays each database in terms of its total percentage of object to the total objects for all databases on the SQL Server.

Location: [Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane](#)

**Database User Analysis**

The Database User Analysis chart displays each database in terms of its total percentage of user accounts to the total user accounts of all databases on the SQL Server.

Location: [Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane](#)

**Database Summary**

The Database Summary Analysis section displays summarized metadata for all defined databases on SQL Server. The table below describes the information available in the Database Summary section:
<table>
<thead>
<tr>
<th><strong>Information</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Created</td>
<td>The date/time when the database was created.</td>
</tr>
<tr>
<td>Status</td>
<td>The status of the database (online, offline, suspect, etc.)</td>
</tr>
<tr>
<td>Database Size (MB)</td>
<td>The total size of the database in MB.</td>
</tr>
<tr>
<td>Log Size (MB)</td>
<td>The total size of the log in MB.</td>
</tr>
<tr>
<td>Tables</td>
<td>The number of all tables in the database.</td>
</tr>
<tr>
<td>Indexes</td>
<td>The number of all indexes in the database.</td>
</tr>
<tr>
<td>Users</td>
<td>The number of all defined user accounts in the database.</td>
</tr>
<tr>
<td>Last Backup</td>
<td>The date/time of the last full backup for the database.</td>
</tr>
<tr>
<td>Autoshrink</td>
<td>This indicates if the database will release space automatically back to the operating system when it does not need it.</td>
</tr>
<tr>
<td>DB Autogrow</td>
<td>This indicates if one or more of the database’s underlying files can automatically grow in size if needed.</td>
</tr>
<tr>
<td>Log Autogrow</td>
<td>This indicates if one or more of the log’s underlying files can automatically grow in size if needed.</td>
</tr>
<tr>
<td>Autocreate Stats</td>
<td>This indicates if object statistics are automatically created for objects in the database.</td>
</tr>
<tr>
<td>Autoupdate Stats</td>
<td>This indicates if object statistics are automatically updated for objects in the database.</td>
</tr>
</tbody>
</table>
The following are things to take note of:

- Any critical database that shows a last full backup date that is older than the database’s required backup needs.
- Any database that shows a status of offline or suspect.
- Any growing database that does not have its database or log files set to automatically grow in size.
- Any dynamic database that does not have its object statistics set to automatically update.

Depending on the situation, you should take the following actions:

For databases that require a full backup, perform a full backup of the database when appropriate. For suspect databases, the steps to handling will vary from one installation to another. However, here are some general guidelines you can use to troubleshoot a suspect database:

- **Begin by examining the SQL Server error log for clues as to what caused the database to be marked as suspect.** It is not unusual for a server to run out of physical disk space on drives used by SQL Server. When this happens, recovery for databases can sometimes fail with the end result being SQL Server marking a database as suspect. To remedy this situation, you should free up space on the identified drives or add files to the newly marked suspect database. This can be accomplished by utilizing the following stored procedures:
  
  - `sp_add_data_file_recover_suspect_db`
  - `sp_add_log_file_recover_suspect_db`

  For SQL Server version 7.0, you will need to use the `sp_resetstatus` stored procedure to reset the suspect status flag for the database in question, use the `alter database` command to add new datafiles to the database, and then stop/start SQL Server.

  Many times, suspect databases are caused by SQL Server not being able to access a database or log file. This happens if a particular physical hard drive has become unavailable, but also can occur if another operating system process has obtained exclusive access to a file. If this scenario proves to be true, once you have ensured that the file(s) are available once again to the operating system, you can use the `sp_resetstatus` stored procedure or the `alter database` command. If any critical, dynamic database or log is found to not have their auto-growth feature enabled, then the DBA can modify the file(s) used by the database to automatically grow by using the `ALTER DATABASE ... MODIFY FILE ... FILEGROWTH` command. You should also ensure that the MAXSIZE setting for each file is set appropriately. If possible, a DBA should keep their databases in AUTO_CREATE_STATISTICS and AUTO_UPDATE_STATISTICS mode. If a database is found without this option set, you can easily change it by using the following commands:

  ```
  EXEC sp_dboption '<database name>','auto create statistics',true
  EXEC sp_dboption '<database name>','auto update statistics',true
  ```

### Error Log Tab

The Error Log tab of the Database Detail includes the following sections:

- **SQL Server Error Log**
- **Error Log Content Analysis**
- **Error Log Volume Analysis**
SQL Server Error Log

SQL Server logs events pertinent to its operations to the SQL Server error log and the operating system application log. Errors encountered by SQL Server are clearly visible in the log, however large logs can be difficult to navigate. The SQL Server Error Log section displays all events for a selected log or just errors.

Location Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Error Log Tab

Metrics You should investigate any positive values reported for errors.

Error Log Volume Analysis

SQL Server logs events pertinent to its operations to the SQL Server error log and the operating system application log. Errors encountered by SQL Server as well as informational message are recorded in the log. The Error Log Volume Analysis section displays a graph that shows the volume amount of messages/errors over the last five days.

Location Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Error Log Tab

Metrics Seeing a disproportionate percentage of messages for one day might indicate that something has, or is occurring that needs investigation.

Error Log Content Analysis

SQL Server logs events pertinent to its operations to the error log and the operating system application log. Errors encountered by SQL Server as well as informational message are recorded in the log. The Error Log Content Analysis section displays a graph that shows percentage of informational messages to errors in the current log.

Location Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Error Log Tab

Metrics You should investigate any indicated errors.

Objects Tab

The following statistics, available on this tab, are duplicates of statistics available on the Objects Tab of the Space View (SQL Server Performance Analyst) page:

- Database Object Summary
- Database Object Detail

SQL Agent Tab

The SQL Agent tab of the Database Detail includes the following sections:
Job/Alert Detail

SQL Server provides the ability to submit and run jobs as well as be notified about certain SQL Server-related events. The Job/Alert Detail section displays information regarding the status of the server’s SQL Agent as well as details for all jobs and alerts that are defined to the system.

Location Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > SQL Agent Tab

SQL Server Job Summary

The SQL Server Job Summary section graphically displays the outcome of all jobs for the last two days, as well as current activity.

Location Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > SQL Agent Tab

Metrics You should investigate any counts noted for failed jobs.

SQL Server Alert Summary

The SQL Server alert summary section graphically displays the number of times that performance and event alerts have fired.

Location Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > SQL Agent Tab

Metrics You should investigate any counts noted for any event.

Backups Tab

The Backups tab of the Database Detail includes the following:

- Backup Detail
- Database Backup Summary
- Log Backup Summary

Backup Detail

The Backup section displays the most recent 25 backups for a selected database. The table below describes the information available on the Backups tab of the Database Detail:
**Database View (SQL Server Performance Analyst)**

<table>
<thead>
<tr>
<th><strong>Information</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Backup Start</td>
<td>The time stamp when the backup began.</td>
</tr>
<tr>
<td>Backup Finish</td>
<td>The time stamp when the backup finished.</td>
</tr>
<tr>
<td>Backup Type</td>
<td>The type of backup (FULL, INCREMENTAL, etc.)</td>
</tr>
<tr>
<td>Backup Size (KB)</td>
<td>The size of the backup, in kilobytes.</td>
</tr>
<tr>
<td>Expiration Date</td>
<td>The expiration date for the backup, if any.</td>
</tr>
</tbody>
</table>

**Location**  
Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Backups Tab

**Metrics**  
Although the needs of an application determine the frequency and type of backup, it is generally recommended that most dynamic databases have a solid plan in place for full and differential backups. For databases requiring point-in-time recovery, a backup plan should also include log backups.

**Database Backup Summary**

The Database Backup Summary section graphically displays the backup successes and failures for database backups over the last week.

**Location**  
Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Backups Tab

**Metrics**  
You should investigate any backup failures.

**Log Backup Summary**

The Log Backup Summary section graphically displays the backup successes and failures for database log backups over the last week.

**Location**  
Microsoft SQL Server Performance Analyst Statistics > Database View (SQL Server Performance Analyst) > Backups Tab

**Metrics**  
You should investigate any backup failures.

**Configuration Tab**

The Configuration tab of the Database Detail displays metadata regarding the hardware characteristics of the SQL Server as well as the SQL Server configuration parameters. The table below describes the information available on the Configuration tab:
### Information | Description
---|---
Parameter | The parameter name.
Value | The value set for the parameter.
Run | The value currently running for the parameter.
Minimum | The minimum value allowed for the parameter.
Maximum | The maximum value allowed for the parameter.
Dynamic | Whether the parameter is dynamic (can be changed without requiring SQL Server to be stopped/started) or not.

## Replication Tab

The Replication tab of the Database Detail provides basic information regarding replication activities that are occurring on the monitored SQL Server.

### Replication Agent Details

The Replication Agent Details section shows information regarding replication. The table below describes the information available on the Replication tab:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agent</td>
<td>The agent performing the replication work.</td>
</tr>
<tr>
<td>Publication</td>
<td>The object being published to a subscribing database.</td>
</tr>
<tr>
<td>Publisher</td>
<td>The SQL Server providing the source material.</td>
</tr>
<tr>
<td>Publisher Database</td>
<td>The database of the SQL Server providing the source material.</td>
</tr>
<tr>
<td>Status</td>
<td>The current status of the replication agent's task.</td>
</tr>
<tr>
<td>Subscriber</td>
<td>The SQL Server requesting the source material.</td>
</tr>
<tr>
<td>Subscriber Database</td>
<td>The database of the SQL Server requesting the source material.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of replication activity (push, pull, etc.)</td>
</tr>
<tr>
<td>Start Time</td>
<td>The start time for the replication task.</td>
</tr>
<tr>
<td>Duration</td>
<td>The duration of the replication task.</td>
</tr>
<tr>
<td>Last Action</td>
<td>The output message for the replication task.</td>
</tr>
</tbody>
</table>
Replication Throughput Details

The Replication Throughput Details section of the Replication tab displays:

- Replication Type
- Measure
- Instance Name
- Value
OS View (SQL Server Performance Analyst)

In many scenarios, an optimally tuned database may not perform well because there are constraints imposed by the system where the database is running. These constraints may include processes competing with the database server for resources (CPU, I/O, or Memory), a slow CPU, insufficient or slow I/O devices, and insufficient memory. The OS Statistics page of Performance Analyst lets you examine operating system metrics for the following platforms:

- AIX
- HP-UX

**Note:** To view processor info and swap disk info on an HP-UX box, you need to login as ROOT in the OS login.

- Linux
- Solaris
- Unix
- Windows XP and 2000

**Note:** The statistics available on the OS page depend on the operating system platform.

**Tip:** If you magnify a graph to change back to the original size or minimize the size, close the OS Page and then reopen it again. Performance Analyst displays the graph in its original form and size.

In addition to a Home page, the OS category of SQL Server Performance Analyst includes the following tabbed pages:

- CPU Tab
- I/O Tab
- Memory Tab
- Network Tab
- Processes Tab
- Space Tab

**Home**

The OS home page includes the following sections:

- Key Resource Usage Pane
OS View (SQL Server Performance Analyst)

- Disk Analysis Pane
- Bottleneck Analysis Pane
- Memory Analysis Pane
- Workload Analysis Pane

**Key Resource Usage Pane**

The following ratios are used on the Performance Analyst OS home page to communicate the general overall performance levels of the operating system:

- Disk Time
- Swap Memory Used
- Processor Time
- Swap Memory Used (Windows)
- Swap Memory Used (AIX, HP-UX, Linux, Solaris, Unix)

**Tip:** To open the CPU tab, right-click Processor Time. To open the I/O tab, right-click Disk Time. To open the Memory tab, right-click Paged Memory Used.

**Disk Time**

The Disk Time statistic is the percentage of elapsed time that the selected disk drive/device was busy servicing read or write requests.

**Location**

Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Home > Key Resource Usage Pane

**Metrics**

You should avoid consistently seeing values for this statistic greater than 90%.

**Correction**

Add more disk drives and partition the files among all of the drives.

**Load Average**

The Load Average statistic represents the system load averages over the last 1, 5, and 15 minutes.
Metrics High load averages usually mean that the system is being used heavily and response time is correspondingly slow.

Processor Time

The Processor Time statistic indicates the percentage of time the processor is working. This counter is a primary indicator of processor activity.

Metrics If your computer seems to be running sluggishly, this statistic could be displaying a high percentage.

Correction Upgrade to a processor with a larger L2 cache, a faster processor, or install an additional processor.

Paged Memory Used

The Paged Memory Used statistic is the ratio of Commit Memory Bytes to the Commit Limit. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk. The commit limit is determined by the size of the paging file. As the paging file increases, so does the commit limit.

Note: This statistic is available for the Windows platform.

Metrics This value displays the current percentage value only and not an average. If the percentage of paged memory used is above 90%, you may be running out of memory.

Correction Increase the size of page file.

Swap Memory Used

The Swap Memory Used statistic is the percentage of swap space currently in use.
If the percentage of swap memory used is above 90%, you may be running out of memory.

**Correction**
Increase the size of your swap files.

### Bottleneck Analysis Pane

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- **Average Disk Queue Length**
- **Interrupts/Sec**
- **Network Output Queue Length/Network Queue Length**
- **Page Faults/Sec**
- **Processor Queue Length**
- **Processor Speed**
- **Processor**

**Tip:** To open the I/O tab, right-click any Details menu item. To open the CPU tab, right-click the Item Processor Queues Length Details menu item. To open the Network tab, right-click Network Output Queues Length.

**Note:** The statistics available in this section depend on the platform of operating system.

### Average Disk Queue Length

The Average Disk Queue Length statistic is the average number of both read and write requests that were queued for the selected disk during the sample interval.
Metrics This metric is useful in identifying I/O related bottlenecks. If the disk queue lengths for certain disks are consistently much higher than others, you may need to redistribute the load among available disks. If the disk queues lengths for all disks are consistently large, and you see a high amount of I/O activity, your disks may be inefficient.

Correction Some things you can do if you have problems with this statistic include: 

- Distribute the data on the disk with the large average disk queue to other disks.
- Upgrade to faster disk(s).

**Interrupts/Sec**

Interrupts/Sec is the average rate, in incidents per second, at which the processor received and serviced hardware interrupts. This value is an indirect indicator of the activity of devices that generate interrupts, such as the system clock, the mouse, disk drivers, data communication lines, network interface cards, and other peripheral devices. These devices normally interrupt the processor when they have completed a task or require attention. Normal thread execution is suspended. The system clock typically interrupts the processor every 10 milliseconds, creating a background of interrupt activity. This statistic shows the difference between the values observed in the last two samples, divided by the duration of the sample interval.

**Network Output Queue Length/Network Queue Length**

The Network Output Queue Length statistic is the number of threads in the processor queue.

**Note:** The name of this statistic depends on the platform of the operating system.
Location  Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than 10 threads per processor is normally acceptable, dependent of the workload.

Correction  A sustained high value in the Processor Queue Length could indicate that a processor bottleneck has developed due to threads of a process requiring more process cycles than are available. If this is the case, you should look at installing a faster (or an additional) processor.

Page Faults/Sec

The Page Faults/Sec statistic is the overall rate faulted pages are handled by the processor. It is measured in numbers of pages faulted per second. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults and soft faults.

Location  Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Correction  If the number of page faults remains consistently high, you can check with your Windows System Administrator for further investigation. Often, large numbers of page faults are not a problem so long as they are soft faults. However, hard faults, that require disk access, can cause delays.

Processor Queue Length

The Processor Queue Length statistic is the number of threads in the processor queue.
Metrics

Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than 10 threads per processor is normally acceptable, dependent of the workload.

Correction

A sustained high value in the Processor Queue Length could indicate that a processor bottleneck has developed due to threads of a process requiring more process cycles than are available. If this is the case, you should look at installing a faster (or an additional) processor.

Processor Speed

The Processor Speed statistic displays the speed of the active processor in MHz. The speed is approximate.

Processor

The Processor Statistic displays the type of processor currently in use, for example, GenuineIntel.

Memory Analysis Pane

The following metrics are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Available Paged Memory (Windows)
- Available Physical Memory
- Available Swap Memory (AIX, HP-UX, Linux, Solaris, Unix)
- Total Paged Memory/Total Swap Memory
- Total Physical Memory

Tip: To open the Memory tab, right-click any Details menu item.
Available Paged Memory

The Available Paged Memory statistic shows the amount of virtual memory available for the processes.

Note: This statistic is available for the Windows platform.

Available Physical Memory

The Available Physical Memory statistic represents the amount of RAM available to all processes.

Available Swap Memory

The Available Swap Memory statistic represents the amount of virtual memory available for the processes.
Metrics If the available Available Swap Memory is less than 10% of total Swap Memory, your system may run out of memory.

Correction Increase the size of swap files.

Total Paged Memory/Total Swap Memory

The Total Paged Memory statistic shows the maximum amount of virtual memory available to all processes.

Note: The name of this statistic depends on the platform of the operating system.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Home > Memory Analysis Pane

Metrics It is recommended that this be 1½ - 3 times the amount of RAM on the system.

Total Physical Memory

The Total Physical Memory statistic shows the amount of physical memory installed on your computer.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Home > Memory Analysis Pane

Metrics This is an informational metric and displays the total amount installed on the machine. Use this value with the available physical memory and paging metrics (Memory details page). If the available physical memory is very small compared to this value, and the paging activity is high, your system may be running low on memory.

Disk Analysis Pane

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Free Disk Space
- Total Disk Space
- Used Disk Space

Tip: To open the Space tab, right-click any Details menu item.

Note: The statistics available in this section depend on the platform of operating system.
Free Disk Space

The Free Disk Space statistic shows the unallocated space, in megabytes on all logical disk drives.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Home > Disk Analysis Pane

Correction There are many things you can do to ensure that a database does not encounter a space problem due to physical space limitations:

If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.

Total Disk Space

Total Disk Space displays the total allocated and unallocated space, in megabytes on all logical disk drives.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Home > Disk Analysis Pane

Correction There are many things a DBA can do to ensure that a database does not encounter a space problem due to physical space limitations, here are two: If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.

Used Disk Space

The Used Disk Space statistic shows the amount of allocated space, in megabytes on all logical disk drives.
Correction

There are many things a DBA can do to ensure that a database does not encounter a space problem due to physical space limitations:

*If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.*

Workload Analysis Pane

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- **Number of Logins**
- **Number of Processes**
- **Top CPU Process**
- **Top I/O Process**

**Tip:** To open the Processes tab, right-click any Details menu item.

**Note:** The statistics available in this section depend on the platform of the operating system.

Number of Logins

This statistic displays the total number of logins on the server.

Number of Processes

This statistic displays the total number of processes on the server.

Top Memory Process

Top Memory Process shows the current process that is consuming the most amount of memory. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of...
memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location  Microsoft SQL Server Performance Analyst Statistics  >  OS View (DBArtisan - SQL Server Performance Analyst)  >  Home  >  Disk Analysis Pane

Metrics  If you are running out of memory on the system, this is a quick way to identify the top memory user. If the displayed process is using a significant portion of the total memory, it could be causing the memory issues.

Top CPU Process

Top CPU Process shows the current process that is consuming the most amount of CPU. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location  Microsoft SQL Server Performance Analyst Statistics  >  OS View (DBArtisan - SQL Server Performance Analyst)  >  Home  >  Disk Analysis Pane

Metrics  If the amount of CPU time used by this process is close to 100% and the CPU usage is very high, this process may be the bottleneck on the server.

Correction  Investigate the process further to see if it is in an inconsistent state. Also, look at minimum requirements for CPU speed for the process. You may need to upgrade your CPU.

Top I/O Process

The Top I/O Process statistic shows the current process that is consuming the most amount of CPU. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location  Microsoft SQL Server Performance Analyst Statistics  >  OS View (DBArtisan - SQL Server Performance Analyst)  >  Home  >  Disk Analysis Pane

CPU Tab

The CPU tab of the OS Detail includes the following sections:

- CPU Events
- CPU Utilization
- Load Averages
The following statistics, available on this tab, duplicate statistics available on the Bottleneck Analysis Pane of the OS View (DBArtisan - SQL Server Performance Analyst) Home page:

- Interrupts/Sec
- Processor Queue Length

Note: The sections available on this tab depend on the platform of operating system.

CPU Utilization

The CPU Utilization section includes the following information:

- % Privileged Time
- % User Time

% Privileged Time

This metric is the percentage of elapsed time that the process threads spent executing code in privileged mode.

Note: For Windows systems, when a Windows system service is called, the service will often run in privileged mode to gain access to system-private data. Such data is protected from access by threads executing in user mode. Calls to the system can be explicit or implicit, such as page faults or interrupts. These kernel commands, are considered privileged to keep the low-level commands executing and prevent a system freeze. Unlike some early operating systems, Windows uses process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. Some work done by Windows on behalf of the application might appear in other subsystem processes in addition to the privileged time in the process.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > CPU Tab

Metrics The ideal range should be 0-40% (less than 40% indicates excessive system activity).

Correction If your CPU consistently runs at less than 40% you may need to upgrade your system to include a faster processor(s).

% User Time

The % User Time statistic is the percentage of elapsed time the processor spends in the user mode. User mode is a restricted processing mode designed for applications, environment subsystems, and integral subsystems. The alternative, privileged mode, is designed for operating system components and allows direct access to hardware and all memory. The operating system switches application threads to privileged mode to access operating system services. This counter displays the average busy time as a percentage of the sample time.
CPU Events

The CPU Events section includes the following information:

- **Context Switches/Sec**
- **Load Averages**
- **System Calls/Sec**

**Note:** The statistics available in this section depend on the platform of operating system.

**Context Switches/Sec**

The Context Switches/Sec section shows the combined rate at which all processors on the computer are switched from one thread to another. Context switches occur when a running thread voluntarily relinquishes the processor, is preempted by a higher priority ready thread, or switches between user-mode and privileged (kernel) mode to use an Executive or subsystem service.

**System Calls/Sec**

System calls are functions which require the services of the operating system. Usually they involve access to some data that users must not be permitted to corrupt or even change.
Correction Try to find a good ratio between the amount of time the operating system runs (fulfilling system calls and doing process scheduling), and the amount of time the application runs. Your goal should be running 60% to 75% of the time in application mode, and 25% to 40% of the time in operating system mode. If you find that the system is spending 50% of its time in each mode, then you should investigate to determine what is wrong.

Load Averages

The Load Average statistic represents the system load averages over the last 1, 5, and 15 minutes.

Metrics High load averages usually mean that the system is being used heavily and the response time is correspondingly slow.

Processes Tab

The Processes tab of the OS Detail page succinctly communicates the general overall performance levels of processes. The columns available in this table depend on the platform of operating system. The table below describes the information available in the table on this tab:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process</td>
<td>The name of the process.</td>
</tr>
<tr>
<td>User</td>
<td>The user of the process.</td>
</tr>
<tr>
<td>ID</td>
<td>The ID Process is the unique identifier of this process. ID Process numbers are reused, so they only identify a process for the lifetime of that process.</td>
</tr>
<tr>
<td>CPU</td>
<td>The CPU is the percentage of elapsed time that all of process threads used the processor to execution instructions.</td>
</tr>
<tr>
<td>User Mode</td>
<td>The User Mode is the percentage of elapsed time that the process threads spent executing code in user mode.</td>
</tr>
<tr>
<td>Memory</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory (MB)</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory Active Memory</td>
<td>Active Memory is the amount of committed virtual memory, in bytes for this process. Active memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive. This counter displays the last observed value only; it is not an average.</td>
</tr>
<tr>
<td>I/O Data</td>
<td>The rate at which the process is reading and writing bytes in I/O operations. This counter counts all I/O activity generated by the process to include file, network and device I/Os.</td>
</tr>
<tr>
<td>Elapsed Time</td>
<td>The total elapsed time, in seconds, that this process has been running.</td>
</tr>
<tr>
<td>Thread Count</td>
<td>The number of threads currently active in this process. An instruction is the basic unit of execution in a processor, and a thread is the object that executes instructions. Every running process has at least one thread.</td>
</tr>
<tr>
<td>Handle Count</td>
<td>The total number of handles currently open by this process. This number is equal to the sum of the handles currently open by each thread in this process.</td>
</tr>
<tr>
<td>Priority</td>
<td>The current base priority of this process. Threads within a process can raise and lower their own base priority relative to the process' base priority.</td>
</tr>
<tr>
<td>Creating Proc ID</td>
<td>The Creating Process ID value is the Process ID of the process that created the process. The creating process may have terminated, so this value may no longer identify a running process.</td>
</tr>
</tbody>
</table>
Page Faults/Sec is the rate at which page faults by the threads executing in this process are occurring. A page fault occurs when a thread refers to a virtual memory page that is not in its working set in main memory. This may not cause the page to be fetched from disk if it is on the standby list and hence already in main memory, or if it is in use by another process with whom the page is shared.

Page File is the current number of kilobytes that this process has used in the paging file(s). Paging files are used to store pages of memory used by the process that are not contained in other files. Paging files are shared by all processes, and the lack of space in paging files can prevent other processes from allocating memory.

Private is the current size, in kilobytes, of memory that this process has allocated that cannot be shared with other processes.

I/O Tab

The I/O tab includes the following sections:

- Average Disk Queue/Total Disk Queue
- LocBytes per I/O Operation
- Disk I/O Time
- Disk Transfers/Sec
- I/O Details
- Transfer Rate

Note: The sections available on this tab depend on the platform of operating system.

I/O Details

The table below describes the information available in this section:
### OS View (SQL Server Performance Analyst)

#### Column | Description
--- | ---
Disk | The disk number assignment.
Reading (KB/s) | The amount of bytes read from the device.
Writing (KB/s) | The amount of bytes written to the device.
Disk Read Time | Disk Read Time is the percentage of elapsed time that the selected disk drive was busy servicing read requests.
Disk Write Time | Disk Write Time is the percentage of elapsed time that the selected disk drive was busy servicing write requests.
Disk Time | Disk Time is the percentage of elapsed time that the selected disk was busy servicing requests.
Avg. Read Queue | Avg. Disk Read Queue Length is the average number of read requests that were queued for the selected disk during the sample interval.
Avg. Write Queue | Avg. Disk Write Queue Length is the average number of write requests that were queued for the selected disk during the sample interval.
Disk Reads/Sec | Disk Reads/Sec is the rate of read operations on the disk.
Disk Writes/Sec | Disk Writes/Sec is the rate of write operations on the disk.

**Note:** The columns available in this table depend on the platform of operating system.

**Location:** [Microsoft SQL Server Performance Analyst Statistics](https://www.embarradero.com/products/sqlserver/analyst) > OS View (DBArtisan - SQL Server Performance Analyst) > I/O Tab

### Transfer Rate

The Transfer Rate section succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading</td>
<td>The average number of bytes transferred from the disk during read operations.</td>
<td>It is measured in number of KBs per second.</td>
</tr>
<tr>
<td>Writing</td>
<td>The average number of bytes transferred to the disk during write operations.</td>
<td>It is measured in number of KBs per second.</td>
</tr>
<tr>
<td>Transferred</td>
<td>The amount of time required to transfer the data between the device’s cache and the actual device media.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.
LocBytes per I/O Operation

The Bytes per I/O Operation section of the OS Detail succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading</td>
<td>The average number of bytes transferred from the disk during read operations.</td>
<td>It is measured in number of bytes per second.</td>
</tr>
<tr>
<td>Writing</td>
<td>The average number of bytes transferred to the disk during write operations.</td>
<td>It is measured in number of bytes per second.</td>
</tr>
</tbody>
</table>

Average Disk Queue/Total Disk Queue

The Average Disk Queue section of the OS Detail page succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average Read Queue</td>
<td>Average Read Queue Length is the average number of read requests that were queued for a particular disk.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system.</td>
</tr>
<tr>
<td>Average Write Queue</td>
<td>Average Write Queue is the average number of write requests that were queued for a particular disk.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system. Contact your Windows System Administrator for assistance in Correction these problems.</td>
</tr>
<tr>
<td>Average Queue</td>
<td>Average time in ms. to service I/O requests which for disks includes seek, rotational latency and data transfer time).</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system. Contact your Unix System Administrator for assistance in Correction these problems.</td>
</tr>
</tbody>
</table>

Note: The statistics available in this section depend on the platform of operating system.
Disk I/O Time

The Disk I/O Time section of the OS Detail page succinctly communicates the general overall performance levels of the disk's I/O. The table below describes the statistics in this section:

**Note:** The statistics available in this section depend on the platform of operating system.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>% Disk Read Time</td>
<td>% Disk Read Time is the percentage of time during the sample interval that the disk is busy servicing read requests.</td>
<td>Use this in conjunction with the % Disk Write Time to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
<tr>
<td>% Disk Write Time</td>
<td>% Disk Write Time is the percentage of elapsed time that the selected disk drive was busy servicing write requests.</td>
<td>Use this in conjunction with the % Disk Read Time to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
<tr>
<td>% Disk Time</td>
<td>% Disk Time is the percentage of time during the sample interval that the disk is busy servicing requests.</td>
<td>Use this statistic to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
</tbody>
</table>

Disk Transfers/Sec

The Disk Transfers/Sec section of the OS Detail page succinctly communicates the general overall performance levels of the disk transfers. The table below describes the statistics in this section.
<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reads/Sec</td>
<td>The rate of read operations on the disk.</td>
</tr>
<tr>
<td>Writes/Sec</td>
<td>The rate of write operations on the disk.</td>
</tr>
<tr>
<td>Transfers/Sec</td>
<td>The rate of transfer operations per second.</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.

**Location:** [Microsoft SQL Server Performance Analyst Statistics](#) > OS View (DBArtisan - SQL Server Performance Analyst) > I/O Tab

### Memory Tab

The Memory tab of the OS Detail page includes the following sections:

- **Buffer Size**
- **Cache Size**
- **Cache Efficiency**
- **Memory Available**
- **Paging Activity**
- **Page Replacements**

The following statistic, available on this pane, duplicates a statistic appearing on the Bottleneck Analysis Pane of the OS View (DBArtisan - SQL Server Performance Analyst) Home page:

- **Page Faults/Sec**

**Note:** The sections available on this tab depend on the platform of operating system.

### Paging Activity

The Paging Activity section includes the following statistics:

- **Blocks Input/Sec**
- **Blocks Output/Sec**
- **Paged In**
- **Paged Out**
- **Pages Input/Sec**
- **Pages Output/Sec**
**Note:** The statistics available in this section depend on the platform of operating system.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

**Blocks Input/Sec**

The Blocks Input/sec statistic is the number of blocks sent to a block device per second.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Correction Although it never hurts to have as much physical memory as your system can handle, here are two things you can check within your system to alleviate the memory bottleneck: Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your swap file. Normally, the bigger the initial size of your swap file, the better, in performance terms.

**Blocks Output/Sec**

The Blocks Output/sec statistic is the number of blocks received from a block device per second.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Correction Although it never hurts to have as much physical memory as your system can handle, here are two things you can check within your system to alleviate the memory bottleneck: Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your swap file. Normally, the bigger the initial size of your swap file, the better, in performance terms.

**Paged In**

The number of disk block paged into core from disk which occurs when the server is experiencing a shortage of RAM. Any nonzero value indicates excessive swap activity. In any virtual memory environment, it is not uncommon to see RAM pages moved out to a swap disk. This is a special disk area in UNIX that’s reserved for holding memory pages so that the processor is capable of addressing RAM in excess of its full capability. While page-out of operations are a normal part of any server’s operations, page-in operations indicate that the real amount of available RAM has been exceeded and that additional RAM pages are required on the server.
Correction High values indicate the possible need to increase the amount of RAM on the system.

**Paged Out**

The number of disk block paged out of core from disk. In any virtual memory environment, it is not uncommon to see RAM pages moved out to a swap disk. This is a special disk area in UNIX that’s reserved for holding memory pages so that the processor is capable of addressing RAM in excess of its full capability. While page-out of operations are a normal part of any server’s operations, page-in operations indicate that the real amount of available RAM has been exceeded and that additional RAM pages are required on the server.

**Pages Input/Sec**

The Pages Input/Sec statistic is the number of pages read from disk to resolve hard page faults. Hard page faults occur when a process requires code or data that is not in its working set or elsewhere in physical memory, and must be retrieved from disk.

**Pages Output/Sec**

The Pages Output/Sec statistic is the number of pages written to disk to free up space in physical memory. Pages are written back to disk only if they are changed in physical memory. A high rate of pages output might indicate a memory shortage.
Location  Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Metrics  Windows NT writes more pages back to disk to free up space when low in physical memory. This counter counts numbers of pages, and can be compared to other counts of pages, without conversion. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Correction  Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Memory Available

The Memory Available section of the OS Detail page succinctly communicates the general overall performance levels of the server’s memory. The statistics available in this section depend on the platform of operating system. The table below describes these statistics:
<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
<th>Correction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical Memory</td>
<td>The Physical Memory statistic is the amount of committed virtual memory, in megabytes. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk.</td>
<td>This counter displays the last observed value only and not an average.</td>
<td>N/A</td>
</tr>
<tr>
<td>Physical</td>
<td>The Physical statistic is the total physical memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Paged Memory</td>
<td>The Paged Memory statistic is the amount of committed virtual memory, in bytes. Used Memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive.</td>
<td>This counter displays the last observed value only; it is not an average.</td>
<td>N/A</td>
</tr>
<tr>
<td>Swap Memory</td>
<td>The Swap Memory statistic is the free, unreserved swap space.</td>
<td>N/A</td>
<td>Increase the size of your swap file or add additional files if you consistently see a shortage of free, unreserved swap space.</td>
</tr>
<tr>
<td>Swap</td>
<td>The Swap statistic is the total swap memory being used.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Total Physical</td>
<td>The Total Physical statistic is the total physical memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Total Swap</td>
<td>The Total Swap statistic is the total swap memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Swap-ins</td>
<td>The number of memory pages paged in from swapspace.</td>
<td>N/A</td>
<td>If the system is consistently low on free memory (over a 30 second average), the memory scheduler will start to swap out processes. Increase the size of your swap file or add additional files.</td>
</tr>
<tr>
<td>Swap-outs</td>
<td>The number of memory pages paged in from swapspace.</td>
<td>N/A</td>
<td>If the system is consistently low on free memory (over a 30 second average), the memory scheduler will start to swap out processes. Increase the size of your swap file or add additional files.</td>
</tr>
</tbody>
</table>
Buffers

The Buffers statistic represents the amount of buffers used by the kernel in kilobytes.

N/A

Page Faults/Sec

The Page Faults/Sec statistic is the overall rate faulted pages are handled by the processor. It is measured in numbers of pages faulted per second. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults and soft faults. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval. If the number of page faults remains consistently high, you can check with your Windows System Administrator for further investigation. Often, large numbers of page faults are not a problem so long as they are soft faults. However, hard faults, that require disk access, can cause delays.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Buffer Size

The Buffer Size statistic represents the amount of cache used by the kernel in kilobytes.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Cache Size

The Cache Size statistic represents the amount of cache used by the kernel in kilobytes.

Location Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Page Replacements

The following statistics are available in this section:

- Memory Freed (Pages/sec)

Memory Freed (Pages/sec)

Freed or destroyed (Kb/s).
Clock Algorithm Scans (Pages/sec)

The VMM uses a technique known as the clock algorithm to select pages to be replaced. This technique takes advantage of a referenced bit for each page as an indication of what pages have been recently used (referenced). When the page-stealer routine is called, it cycles through the PFT, examining each page’s referenced bit.

Cache Efficiency

The Cache Efficiency section of the Memory tab succinctly communicates the general overall performance levels of the server’s memory. The following statistics are available in this section:

- **Copy Read Hits %**
- **Data Map Hits %**
- **MDL Read Hits %**
- **Pin Read Hits %**

Copy Read Hits %

The Copy Read Hits % statistic is the percentage of cache copy read requests that hit the cache and does not require a disk read to provide access to the page in the cache.

**Metrics** When the page is pinned in the memory, the page's physical address in the file system cache will not be altered. A copy read is a file read operation where a page in the cache is copied to the application’s buffer. Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

**Correction** Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

Data Map Hits %

The Data Map Hits % statistic is the percentage of data maps in the file system cache that could be resolved without having to retrieve a page from the disk.
OS View (SQL Server Performance Analyst)

Location  Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Metrics Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

Correction Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

**MDL Read Hits %**

The MDL Read Hits % statistic is the percentage of Memory Descriptor List Read requests to the file system cache that hit the cache and does not require disk access to provide memory access to the pages in the cache.

Location  Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Metrics Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

Correction Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

**Pin Read Hits %**

The Pin Read Hits % statistic is the percentage of pin read requests that hit the file system cache and does not require a disk read in order to provide access to the page in the file system cache.

Location  Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab

Metrics Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

Correction Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

**Space Tab**

The Space tab of the OS Detail page includes the following sections:

- Disk Space Free
- Disk Space Detail
- Device Summary
OS View (SQL Server Performance Analyst)

- **Device Detail**

**Disk Space Free**

The Disk Space Free metric displays the amount of free disk space in megabytes.

Location: [Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab](#)

**Disk Space Detail**

The Disk Space Detail section of the Space tab succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition</td>
<td>The drive letter of the disk.</td>
</tr>
<tr>
<td>Local Filesystem</td>
<td>The name of the file system.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of file system.</td>
</tr>
<tr>
<td>Total Space</td>
<td>Total size of the disk/device's capacity expressed in MBs.</td>
</tr>
<tr>
<td>Used Space</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free Space</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
<tr>
<td>Capacity</td>
<td>The percentage of space used on the device.</td>
</tr>
<tr>
<td>Mounted On</td>
<td>The mount point of the device.</td>
</tr>
</tbody>
</table>

Location: [Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab](#)

**Device Summary**

The Device Summary section of the Space tab displays a bar chart for all devices. The Device Summary section succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Used</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
</tbody>
</table>

Location: [Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Memory Tab](#)
Device Detail

The Device Detail section of the Space tab succinctly communicates the general overall performance levels of the server’s disks and space allotment. The statistics available in this section depend on the platform of operating system. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition</td>
<td>The drive letter of the disk.</td>
</tr>
<tr>
<td>Local Filesystem</td>
<td>The name of the file system.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of file system.</td>
</tr>
<tr>
<td>Total Space</td>
<td>Total size of the disk/device's capacity expressed in MBs.</td>
</tr>
<tr>
<td>Used Space</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free Space</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
<tr>
<td>Capacity</td>
<td>The percentage of space used on the device.</td>
</tr>
<tr>
<td>Mounted On</td>
<td>The mount point of the device.</td>
</tr>
</tbody>
</table>

Network Tab

The Network tab of the OS Detail page succinctly communicates the general overall performance levels of the server’s networking. The Network tab of the OS Detail page includes the following sections:

- Network Details
- Packet Collisions
- Packet Discards
- LPacket Errors
- Transmission Rate
- Transmission Rate (Bytes)
- Transmission Queue Length
**Note:** The sections available on this tab depend on the platform of operating system.

### Network Details

The statistics available in this section depend on the platform of operating system. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network Interface</td>
<td>The name of network interface.</td>
</tr>
<tr>
<td>INET Address/Address</td>
<td>The IP address assigned to the network interface.</td>
</tr>
<tr>
<td>Pkts Sent/Sec</td>
<td>The number of packets sent per second.</td>
</tr>
<tr>
<td>Pkts Received/Sec</td>
<td>The number of packets received per second.</td>
</tr>
<tr>
<td>Sent (KB/Sec)</td>
<td>The number of bytes sent per second.</td>
</tr>
<tr>
<td>Received (KB/Sec)</td>
<td>The number of bytes received per second.</td>
</tr>
<tr>
<td>Out Pkts Discarded</td>
<td>The number of outbound packets discarded.</td>
</tr>
<tr>
<td>In Pkts Discarded</td>
<td>The number of inbound packets discarded.</td>
</tr>
<tr>
<td>Out Pkt Errors</td>
<td>The number of outbound packet errors.</td>
</tr>
<tr>
<td>In Pkt Errors</td>
<td>The number of inbound packet errors.</td>
</tr>
<tr>
<td>Queue Length</td>
<td>The queue length.</td>
</tr>
<tr>
<td>Collisions</td>
<td>The number of collisions.</td>
</tr>
<tr>
<td>Packets Discarded</td>
<td>The number of packets discarded.</td>
</tr>
</tbody>
</table>

**Location** [Microsoft SQL Server Performance Analyst Statistics](https://www.embarcadero.com/products/dbe/vbsql) > OS View (DBArtisan - SQL Server Performance Analyst) > Network Tab

### Transmission Rate

The Transmission Rate section of the Network tab succinctly communicates the packet transmission rate. The following statistics are available in this section:

- **Packets Sent/Sec**

### Packets Sent/Sec

The Packets Sent/Sec statistic is the number of packets sent over each network adapter per second.
Packets Received/Sec

The Packets Received/Sec statistic is the number of packets received over each network adapter per second.

Transmission Rate (Bytes)

The Transmission Rate (Bytes) section of the Network tab succinctly communicates the packet transmission rate. The following statistics are available in this section:

- Received (KB/Sec)
- Sent (KB/Sec)

Sent (KB/Sec)

The Sent (KB/Sec) statistic is the rate at which bytes are sent over each network adapter including framing characters.

Received (KB/Sec)

The Received (KB/Sec) statistic is the rate at which bytes are received over each network adapter, including framing characters.

Transmission Queue Length

The number of pending outgoing packets on either the software transmit queue or the hardware transmit queue.
Packet Collisions

A collision occurs when two devices on the network sense that the network is idle and end up trying to send data at the same time. Some collisions are normal on a repeated network, but excess collisions can cause serious performance problems.

Correction

Contact your network administrator if there is high rate of persistent Packet Collisions.

Packet Discards

The Packet Discards section of the Network tab succinctly communicates the packet discard rate. The following statistics are available in this section:

- **Inbound Packets Discarded**
- **Outbound Packets Discarded**
- **Packet Discards**

Outbound Packets Discarded

The Outbound Packets Discarded statistic is the number of outbound packets that were discarded even though no errors had been detected to prevent from being transmitted.

Correction A possible reason for discarding such a packet could be to free up buffer space.

Inbound Packets Discarded

Received Packets Discarded is the number of received packets that were discarded even though no errors had been detected to prevent from being transmitted.

Correction A possible reason for discarding such a packet could be to free up buffer space.

Packet Discards

The Packet Discards statistic represents the number of network packets discarded.
LPacket Errors

Location: Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Network Tab

Correction: Contact your network administrator if there is a high rate of persistent packet discards.

The Packet Errors section of the Network tab succinctly communicates the packet error rate. The following statistics are available in this section:

- **Inbound Packet Errors**
- **Outbound Packet Errors**

Outbound Packet Errors

The Outbound Packet Errors statistic is the outbound packets that contained errors preventing them from being deliverable to a higher-layer protocol.

Location: Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Network Tab

Inbound Packet Errors

The Packets Received Errors statistic is the received packets that contained errors preventing them from being deliverable to a higher-layer protocol.

Location: Microsoft SQL Server Performance Analyst Statistics > OS View (DBArtisan - SQL Server Performance Analyst) > Network Tab
One or two bad queries can cause a lot of trouble for the remaining sessions in a database, and so can one or two bad queries. It is important to find them before they get into a production system, but sometimes a few sneak through.

By applying custom filters and performance-related thresholds, the Top SQL view locates inefficient SQL. By applying filters to certain I/O and statistical counters, you hope to isolate queries that far exceed their nearest competitors in the same area (like disk reads). When you find them, you should reduce the number of sorts a query performs. Or, for a query that returns only a few records, you should try to minimize the number of rows a query processes.

Top SQL displays requested SQL for SQL Server datasources. The following tabs are available on the Top SQL page:

- Summary Tab
- Criteria Tab
- SQL Details Tab

Summary Tab

The Summary tab of the Top SQL page includes the following sections:

- Top SQL Statements - SQL Server
- Top SQL Details

Top SQL Statements - SQL Server

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end user response times.

Before you can identify problem SQL in your database, you have to ask the question of what ‘bad SQL’ is. What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every Oracle professional’s satisfaction. The table below describes some general criteria you can use when evaluating the output from various database monitors or personal diagnostic scripts:
### Criteria

<table>
<thead>
<tr>
<th>Description</th>
<th>Overall Response (Elapsed) Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is how much time the query took to parse, execute, and fetch the data needed to satisfy the query. It should not include the network time needed to make the round trip from the requesting client workstation to the database server.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
<th>CPU Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is how much CPU time the query took to parse, execute, and fetch the data needed to satisfy the query.</td>
<td></td>
</tr>

<table>
<thead>
<tr>
<th>Description</th>
<th>Physical I/O</th>
</tr>
</thead>
<tbody>
<tr>
<td>Often used as the major statistic in terms of identifying good vs. bad SQL, this is a measure of how many disk reads the query caused to satisfy the user’s request. While you certainly want to control disk I/O where possible, it is important that you not focus solely on physical I/O as the single benchmark of inefficient SQL. Make no mistake, disk access is slower than memory access and also consumes processing time making the physical to logical transition, but you need to look at the entire I/O picture of a SQL statement, which includes looking at a statements’ logical I/O as well.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
<th>Logical I/O</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is a measure of how many memory reads the query took to satisfy the user’s request. The goal of tuning I/O for a query should be to examine both logical and physical I/O, and use appropriate mechanisms to keep both to a minimum.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
<th>Repetition</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is a measure of how often the query has been executed. A problem in this area is not as easy to spot as the others unless you know your application well. A query that takes a fraction of a second to execute may still be causing a headache on your system if it is executed erroneously over and over.</td>
<td></td>
</tr>
</tbody>
</table>

There are other criteria that you can examine like sort activity or access plan statistics (that show items like Cartesian joins and the like), but more often than not, these measures are reflected in the criteria listed above.

Fortunately, Microsoft records some of these statistics and Performance Analyst computes the rest, which makes tracking the SQL that has been submitted against a SQL Server much easier.
When you begin to look for inefficient SQL in a database, there are two primary questions you need to answer: 

1. **What has been the worst SQL that’s historically been run in my database?**
2. **What is the worst SQL that’s running right now in my database?**

When correcting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It may be that the query is in an inefficient Transact SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.

### Top SQL Details

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured database down in terms of end user response times.

Before you can identify problem SQL in your database, you have to ask the question of what ‘bad SQL’ is. What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every SQL Server professional’s satisfaction. The Top SQL Details Section displays the top SQL statements across various performance categories. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top For</td>
<td>Indicates the performance category for the SQL statement.</td>
</tr>
<tr>
<td>Usage</td>
<td>This displays the percent usage for this SQL statement in this performance category.</td>
</tr>
<tr>
<td>SQL text</td>
<td>A snippet of the actual SQL statement or code object (procedure, etc.)</td>
</tr>
<tr>
<td>Total Reads</td>
<td>The total physical reads caused by the statement since monitoring began.</td>
</tr>
<tr>
<td>Total Writes</td>
<td>The total physical writes caused by the statement since monitoring began.</td>
</tr>
<tr>
<td>Executions</td>
<td>The total number of times the statement or code object has been executed since monitoring began.</td>
</tr>
<tr>
<td>Avg CPU Time</td>
<td>The average CPU time used by the statement each time it is executed.</td>
</tr>
<tr>
<td>Avg Elapsed Time</td>
<td>The average elapsed response time experienced each time the statement is executed.</td>
</tr>
</tbody>
</table>
When you begin to look for inefficient SQL in a database, there are two primary questions you need to answer: What has been the worst SQL that’s historically been run in my database? What is the worst SQL that’s running right now in my database? When Correction a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It may be that the query is in an inefficient Transact SQL loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.

Criteria Tab

The Top SQL view displays all SQL running or executed in the current datasource. You can use the lists and boxes to reorder the display according to your specific needs. The Criteria tab of the Top SQL page includes the following sections that you can mix and match to give you the information you want to find:

- Demographic Criteria
- Statistical Criteria
- Sort Criteria

SQL Details Tab

The SQL Details tab of the Top SQL page includes the following sections:

- Top SQL Results

Top SQL Results

Overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements or stored procedures can drag an otherwise well-configured database down in terms of end user response times.

Before you can identify problem SQL in your database, you have to ask the question of what ‘bad SQL’ is. What criteria do you use when hunting for problem SQL in critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every SQL Server professional’s satisfaction. The Top SQL results grid displays the top SQL statements across various performance categories. The table below describes the information available in this section:
### Information | Description
--- | ---
SQL Text | A snippet of the full SQL statement. Clicking the statement will cause the full statement to be presented in the Selected SQL Text grid.
Database | The database where the statement or code object’s execution originated.
Avg Reads | The average physical reads caused by the statement each time it is executed.
Total Reads | The total physical reads caused by the statement since monitoring began.
Avg Writes | The average physical writes caused by the statement each time it is executed.
Total Writes | The total physical writes caused by the statement since monitoring began.
Executions | The total number of times the statement or code object has been executed since monitoring began.
Avg Elapsed Time | The average elapsed response time experienced each time the statement is executed.
Elapsed Time | The total elapsed response time over all executions.
Avg CPU Time | The average CPU time used by the statement each time it is executed.
Total CPU Time | The total CPU time over all executions.
First Start Time | The date/time when the statement was first executed.

Performance Analyst for Sybase ASE Tutorial

Embarcadero Performance Analyst provides key insight into the complex world of database performance. Running inside the Embarcadero DBArtisan console, or standalone in a Web browser, Performance Analyst helps you pinpoint performance problems that threaten a database’s availability or response times. The powerful analysis facilities will satisfy advanced experts, yet novices will find Performance Analyst’s interface easy to use and the expert help a welcome aid to troubleshooting difficult performance issues.

About This Performance Analyst for Sybase ASE Tutorial

This tutorial is intended to help you get started with Embarcadero Performance Analyst. After completion of this tutorial, you will have the foundation you need to explore the many features and benefits of Performance Analyst. You will have learned how to accurately monitor your database using the most popular performance methodologies in use today. You will know how to drill down into the many layers of database performance and also be able to locate performance issues in your database in a fast and effective manner. Finally, you’ll understand how to fix performance problems using the integration that exists between Performance Analyst and Embarcadero DBArtisan.

This tutorial is divided into 7 sections.

- Session 1: Getting Started With Performance Analyst for Sybase ASE
- Session 2: Using Ratio-based Performance Analysis in Performance Analyst for Sybase ASE
- Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Sybase ASE
- Session 4: Using Workload Performance Analysis in Performance Analyst for Sybase ASE
- Session 5: Using Operating System Performance Analysis in Performance Analyst for Sybase ASE
- Session 6: Identifying and Getting Help With Performance Problems Using Performance Analyst for Sybase ASE
- Session 7: Fixing Identified Problems

You can use this basic tutorial as a roadmap of product highlights.

After starting this tutorial, you can select Help from the menu to find many additional resources that complement and build on many of the activities shown in this brief guide.
Session 1: Getting Started With Performance Analyst for Sybase ASE

Download and Install

You can obtain the latest version of Performance Analyst by downloading the DBArtisan software from the Embarcadero Web site at http://www.embarcadero.com/downloads/downloaddbartisan.asp. Performance Analyst runs fully contained within DBArtisan so you will need the DBArtisan product to use Performance Analyst (although Performance Analyst can also run in standalone fashion within a Microsoft Internet Explorer Web browser).

Click Download, and follow the steps indicated. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for 14 days. After that time, a permanent license is needed.

Overview of Performance Analyst for Sybase ASE

When DBArtisan is connected to a Sybase ASE database, you can open Performance Analyst two ways:

1. On the Analyst toolbar click the Performance Analyst icon.

OR

2. On Utilities menu, select Performance Analyst.

For Performance Analyst to work, several procedures need to be installed by the SA account. When Performance Analyst is first invoked, it will check for the presence of this package and if it has not been installed, the product will prompt you to install it. Once created, any account with access to these procedures can monitor databases using Performance Analyst. No other objects need to be installed on a monitored database.

Performance Analyst for Sybase ASE Product Navigation

Navigating through Performance Analyst is easily accomplished through two main mechanisms:

1. The main Performance Analyst toolbar contains buttons that invoke the major performance analysis views within the product as well as frequently used actions like Refresh and Performance Threshold Customizations.

2. Positioning the mouse pointer on any area within Performance Analyst and clicking the right mouse button will bring up a navigation menu that allows you to easily move between any of the main Performance Analyst home pages and
drill down views. The right mouse menu also contains context sensitive options like drilling down further into a particular statistic, copying the display to a text file, and more.

Proceed to Session 2: Using Ratio-based Performance Analysis in Performance Analyst for Sybase ASE

Session 2: Using Ratio-based Performance Analysis in Performance Analyst for Sybase ASE

Ratio-based analysis has been around for many years, and used to be the only technique database administrators used when they were called on to diagnose the cause of a database slowdown. Performance ratios are very good roll-up mechanisms for busy DBAs, making possible the analysis-at-a-glance approach, however ratios must be computed correctly for them to be meaningful. Key ratios in Performance Analyst are calculated using delta statistics, which is superior to computing ratios with cumulative values. Delta statistics, which are values derived by using the before and after measures in each statistical refresh done in Performance Analyst, lets you see changes in performance metrics that would otherwise be invisible if cumulative statistics were used. Performance Analyst makes it easy to see the ratios that are computed with delta statistics vs. cumulative. A triangle symbol denotes a delta-based statistic, while square symbols represent a cumulative-based measure.

Ratio-based analysis is available for all performance categories (memory, etc.) where ratios can assist in determining the performance level of a database. For example, if you would like to see memory-specific ratios, on the Performance Analyst toolbar click Memory. Performance Analyst displays the Memory home page that showcases all important memory-related ratios.

Obtaining Detail Information for a Ratio Using Performance Analyst for Sybase ASE

A ratio gives you a global picture for a particular performance measure. However, you often need more information regarding a statistical measure so you can make an informed decision. Performance Analyst has easy-to-use drill down features that make obtaining detailed information for various ratios a breeze.

For example, to view more information for the Data Cache Hit Ratio statistic, do the following:

1. On either the Main Home page or the Memory Home page, locate the Data Cache Hit Ratio statistic.
2. Position the pointer over the statistic.

The pointer changes to a hand symbol.
Session 2: Using Ratio-based Performance Analysis in Performance Analyst for Sybase ASE

3. Double-click the left mouse button.
Performance Analyst opens the **Data Cache** tab of the memory drill down view.

OR

4. Right-click the statistic, select Details.

OR

5. Select Navigate to, Memory, Data Cache.
Performance Analyst opens the **Data Cache** tab of the memory drill-down view.

Proceed to **Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Sybase ASE**
Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for Sybase ASE

When a Sybase ASE database is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things, or it can be an indicator that a database bottleneck exists. Bottleneck analysis is a valid method of measuring performance because it helps you track where a database and user sessions have been spending their time. If latch contention or heavy table-scan activity has been dragging a database’s performance down, you can use bottleneck analysis to confirm the actual root cause.

Performance Analyst uses three broad areas of metrics to form its bottleneck analysis. The first are contentions and conflicts as reported in Sybase’s monitoring sp_sysmon procedure, as well as overall lock statistics. The second is the Sybase wait event interface (available only in Sybase 12.5.03 and higher), which displays where the database and user sessions have been bottlenecked. A third area of bottleneck information has to do with space related bottlenecks like databases and transaction logs that are running low on available free space.

Performance Analyst prominently displays bottleneck analysis on every performance home page. The Main home page, displays a summary of all key bottlenecks threatening the database. You can also see specific bottlenecks for memory, I/O, space, objects, and users by navigating to each home page and viewing the Bottleneck Analysis section for that home page. For example, to see bottlenecks that specifically relate to I/O, do the following:

1. On the toolbar, click the I/O button.
2. Locate the Bottleneck Analysis section at the lower-left portion of the screen.

The I/O bottleneck analysis section shows the I/O related headaches, along with the most active devices.

Obtaining Detail on System Bottlenecks Using Performance Analyst for Sybase ASE

You can easily obtain more information regarding global bottlenecks that are plaguing a database by drilling down into a particular bottleneck metric. For example, if you would like to see more data regarding the current top system bottlenecks, do the following:

1. Right-click anywhere in Performance Analyst, point to Users, and then click System Waits.

Performance Analyst opens the System Waits view.
The System Waits view (available in Sybase ASE 12.5.03 and higher with the MDA monitoring views installed) displays critical details regarding all the wait events that Sybase has recorded. You can easily see what events that occurred the most often as well as the events that have accumulated the most wait time.

**Tip:** If you would like to see an expanded view of the System waits grid shown on the top of the System Waits view, click the Expand button located at the top right corner of the section. All section views in Performance Analyst can be maximized/minimized using this control.

### Viewing Detail for Session Bottlenecks Using Performance Analyst for Sybase ASE

Not only can you obtain detail information for system bottlenecks, but you can also use Performance Analyst to get drill down information regarding session-level bottlenecks. There are several layers to session-level details you can view.

To see more information regarding session-level waits, do the following:

1. Right-click anywhere in Performance Analyst, point to Users, and then click Session Waits.

Performance Analyst opens the Session Waits drill-down view.

When you are in the Session Waits drill down view, to drill further into a session’s details, do the following:

1. In the Historical Waits or Current Waits grid, select a session that appears to be experiencing critical waits.

2. Double-click the session or right-click, and then select Details.

Performance Analyst opens a drill-down view that shows key statistics for the selected session, including its current work activities, wait events, and SQL statements.

Proceed to [Session 4: Using Workload Performance Analysis in Performance Analyst for Sybase ASE](#)
Session 4: Using Workload Performance Analysis in Performance Analyst for Sybase ASE

Key ratios give you a global perspective on database activity. Bottleneck analysis gives you insight into things that are holding up user activity and throughput. But another technique is necessary if a database professional is to really get a handle on what’s occurring inside a badly performing database.

Workload analysis involves the investigation of two critical areas of a database’s performance:

- Session resource consumption and activity
- SQL execution (if available)

Without looking at these two key performance categories, you can miss a lot of what could be responsible for perceived performance problems. When performance on a database takes a sudden nosedive, it is not uncommon to find one or two sessions that are causing the bulk of the workload. Finding these processes can be easily accomplished by viewing session metadata coupled with resource consumption and statistical execution statistics.

Pinpointing Top Resource Consumers

Performance Analyst identifies top resource consumers in a couple of different ways. On the main home page, Performance Analyst highlights the top resource sessions across I/O, memory usage, and CPU consumption. The percentage used across all statistical categories are displayed so a DBA can immediately pinpoint a session that is using all or most of a particular resource. The top resource sessions are also displayed on the memory, I/O, and other home pages as well with a listing for the top sessions for that category (for example, the top memory users appear on the memory home page, etc.)

Getting Workload Details

Performance Analyst offers several details on top resource sessions in addition to the summaries provided on each home page. A detailed and flexible top sessions view lets you view a summary of all the major resource sessions on the database as well as every critical detail regarding each session connected to the database.

Further drill downs are available that highlight specific details regarding each session’s activities and submitted SQL. To see detailed information regarding a session identified in one of Performance Analyst’s Workload Analysis sections, do the following:

1. In a Workload Analysis display, position the pointer over one of the processes.
2. Double-click the process or right-click, and then select Details.
If you want like to see all key workload analysis metadata for sessions, do the following:

1. On the toolbar, click the Top Sessions button.

OR

2. Right-click anywhere in Performance Analyst, point to Users, and then click Session Waits.

Proceed to Session 5: Using Operating System Performance Analysis in Performance Analyst for Sybase ASE
Session 5: Using Operating System Performance Analysis in Performance Analyst for Sybase ASE

In many scenarios, an optimally tuned database may not perform well because there are constraints imposed by the system where the database is running. These constraints may include processes competing with the database sever for resources (CPU, I/O or Memory), a slow CPU, insufficient I/O devices, and insufficient memory. Performance Analyst allows you to examine the relevant operating system metrics for Windows Platforms (NT /2000/XP/2003) as they relate to Sybase ASE.

To view the operating system metrics of the machine hosting the Sybase ASE server you are monitoring, do the following:

1. Click the OS Performance Analyst toolbar button.

OR

2. Navigate to the OS Home Page by going to OS, and then Home.

Note: The first time you invoke the OS feature you will be prompted for an operating system login. Please specify the correct operating system, host name, username and password, and protocol.

The Operating System home page has been designed in a similar fashion as the datasource home page. On this page you can see the pertinent operating system metrics displayed in five quadrants broken down into the following categories:

- Resource Usage
- Memory Analysis
- Disk Analysis
- Workload Analysis
- Bottleneck Analysis

Obtaining Details on the Operating System Using Performance Analyst for Sybase ASE

You can easily obtain more information regarding operating system problems that are degrading database performance by drilling down into a particular analysis quadrant. For example if you’d like to see more information regarding the processes running on the host machine, do the following:

1. Navigate to the Performance Analyst Operating System home page.

2. Double-click the Top Memory Process in the Workload Analysis quadrant.
Performance Analyst opens the Processes detail view.

OR

3. Right-click anywhere in Performance Analyst and select the Navigate to, OS, and then Processes.

The Processes detail tab shows all the processes on the host machine. From this view you can easily determine which processes are showing high marks in I/O or CPU, for example, by simply double clicking on the column headers and sorting the processes in ascending or descending order.

Proceed to Session 6: Identifying and Getting Help With Performance Problems Using Performance Analyst for Sybase ASE
Session 6: Identifying and Getting Help With Performance Problems Using Performance Analyst for Sybase ASE

You do not have to be an advanced expert in performance tuning to spot trouble in a database if you use Performance Analyst. There are a number of mechanisms in the tool that help you quickly locate areas of concern within a database.

Using the Alarm Log in Performance Analyst for Sybase ASE

Performance Analyst has a central and flexible alarm log that lists every performance violation found in all monitored databases. Unlike some products that only show you alarms for a particular database, Performance Analyst lists all alarms for each database you are monitoring in one central log so you can see every problem in one place. To view the Performance Analyst Alarm log, do the following:

1. On the toolbar, click the Alarms button.

Once in the Alarm log, you can perform a number of actions including:

- Selecting an alarm and viewing the application page that shows details regarding the metric in violation.
- Filtering the types of alarms shown through the Options dialog.
- Clearing all current alarms.
- Copying or saving the Alarm log into a different format.

To select any of these options, do the following:

1. Position the pointer over any area of the Alarm Log.
2. Right-click and in the shortcut menu, select an option.

Recognizing Performance Violations

Performance Analyst makes it easy to visually pinpoint performance violations in a database. Any statistic that does not conform to your predefined performance standards is colorized in any view that it appears so you can easily see potential troublespots.

The colors used to highlight a particular performance violation depend on the severity of the problem. Performance Analyst uses several layers of performance standards/threshold violations with each layer being represented by a different color. You can control everything regarding threshold violations, including how thresholds are determined, their color representation in Performance Analyst’s display, and more by using the Threshold Template feature of Performance Analyst.
How can Performance Analyst inform you of performance violations in your database if you minimize the product to your desktop and are working on other things? Even if Performance Analyst is not right in front of you, it can still let you know that a problem has been found in your database through the systray alarm icon. When Performance Analyst detects a problem in one of your databases, one of the things the product does is enable an alarm icon in your workstation’s systray area that communicates the presence of alarms in your database. So even if the Performance Analyst interface is not in sight, the product can let you know that something in your database requires attention.

Creating Threshold Templates

How does Performance Analyst know what to signal as a problem in a database? It uses predefined performance standards that you define and enforce. All of this is accomplished by using Performance Analyst’s Threshold templates. A template is a set of performance metrics and their thresholds that can be reused to enforce performance standards across any number of databases. Embarcadero provides a default performance template that contains nearly all of the most-watched performance statistics so you can begin monitoring with confidence right out of the box. However, you can create your own Threshold templates so you only are alerted to performance violations that are important to you and your particular environment.

To view or create Threshold templates, do the following:

1. On the toolbar, click the Thresholds button.

Performance Analyst opens the Threshold Template Properties dialog.

The Threshold Template Properties dialog lets you select the options to add or edit templates, as well as other maintenance options. For example, you can copy the original Embarcadero Threshold template and modify it to fit your own needs. You can control what statistics are sampled for performance violations as well as the levels of severity you would like reported. Once you are satisfied with your template, you can save it and then apply it to one or more datasources in one action to immediately begin enforcing your performance standards.

Getting Help With Performance Problems

As databases become more complex, so do the problems that plague them. Knowing what to do for a particular performance problem can be hard in some cases, but Performance Analyst helps by providing a complete set of expert help that you can use as a guide when performance problems occur. To obtain expert help for any statistic shown in Performance Analyst, do the following:

1. Position the pointer over a statistic that you need help.

2. Right-click and select Help.

The Expert Help gives you a general description of the statistic, the range of values that are considered optimal, and some suggestions on how to fix a problem situation. Expert help can also be invoked for any of the Ratio, Bottleneck, SQL, or Workload Analysis
sections shown on every home page by clicking on the help icon for that section, which is located at the top right corner of the section.

Proceed to Session 7: Fixing Identified Problems

Session 7: Fixing Identified Problems

Finding performance problems is one thing, but fixing them is another. Many performance monitors point out a particular problem in a database, but then offer no way to actually correct the situation. Such is not the case with Performance Analyst. Because of its tight integration with DBArtisan, certain problems found in Performance Analyst can be visually corrected by DBArtisan.

A Space Problem Correction Example

If a Sybase ASE Server tablespace is about to run out of free space, Performance Analyst can issue an alarm that a space shortage exists. Once the space problem has been identified, do the following:

1. On the Space home page toolbar, click the Space button.

2. In the Space Analyst grid, right-click a tablespace, and then select Manage with DBArtisan.

DBArtisan opens an editor where you can perform corrective actions, such as enabling Autoextend for the tablespace, resizing the tablespace’s existing datafile(s), or adding a new datafile for the tablespace.
Sybase ASE Performance Analyst Statistics

This section includes expert help for all Sybase ASE categories and statistics in the Embarcadero Performance Analyst views and pages. This help is divided into the following sections:

- Home View (Sybase ASE Performance Analyst)
- Memory View (Sybase ASE Performance Analyst)
- I/O (Sybase ASE Performance Analyst)
- Space (Sybase ASE Performance Analyst)
- Databases (Sybase ASE Performance Analyst)
- Users (Sybase ASE Performance Analyst)
- OS (Sybase ASE Performance Analyst)
- Top SQL Statistics (Sybase ASE Performance Analyst)

**Note:** Sybase ASE 12.5.0.3 users should make sure their MDA tables are properly configured so they can see all available statistics. Please refer to the instructions for Enabling MDA Tables.
Enabling MDA Tables

In ASE 12.5.0.3, a new feature called "MDA tables" was introduced. These proxy tables are mapped to RPCs which provide access to low-level monitoring information about the server. Refer to Sybase documentation for details on MDA tables. For assistance, see Accessing Third Party Documentation.

DBArtisan’s Performance Analyst for Sybase ASE requires these tables be installed to enable several statistics, for example the Top SQL view.

Please follow the instructions below to install and configure these tables.

1. Ensure the ‘enable cis” configuration parameter is set to 1.

   sp_configure 'enable cis'
   go

2. Add the ‘loopback’ server name alias.

   if not exists (select 1 from master..sysservers where srvname = "loopback")
   BEGIN
   exec sp_addserver "loopback", null, <enter your server name>
   END

3. Install the MDA tables.

   The script can be found in the following location:

   $SYBASE/$SYBASE_ASE/scripts/installmontables.

4. Assign the ‘mon_role’ to logins allowed MDA access.

   Note: The ‘sa’ login requires this grant as well.

   use master
   go
   grant role mon_role to sa
   go

5. Enable the following configuration parameters.

   exec sp_configure "enable monitoring", 1
   exec sp_configure "sql text pipe active", 1
   exec sp_configure "sql text pipe max messages", 2000
   exec sp_configure "plan text pipe active", 1
Enabling MDA Tables

exec sp_configure "plan text pipe max messages", 2000
exec sp_configure "statement pipe active", 1
exec sp_configure "statement pipe max messages", 2000
exec sp_configure "errorlog pipe active", 1
exec sp_configure "errorlog pipe max messages", 2000
exec sp_configure "deadlock pipe active", 1
exec sp_configure "deadlock pipe max messages", 2000
exec sp_configure "wait event timing", 1
exec sp_configure "process wait events", 1
exec sp_configure "object lockwait timing", 1
exec sp_configure "SQL batch capture", 1
exec sp_configure "statement statistics active", 1
exec sp_configure "per object statistics active", 1
exec sp_configure "max SQL text monitored", 2000
Home View (Sybase ASE Performance Analyst)

The Embarcadero Performance Analyst Home view lets you review availability and overall performance of all monitored databases from a single window. Statistics on the Home view are organized into the following categories:

- Bottleneck Analysis Pane
- Key Ratio Analysis Pane
- I/O Analysis Pane
- Storage Analysis Pane
- Workload Analysis Pane

Key Ratio Analysis Pane

Database performance analysts typically use one of two methods for examining the performance levels of a database - ratio-based or wait/bottleneck-based. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for busy DBAs to use for at-a-glance performance analysis. Many DBAs have large database farms to contend with and cannot spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving DBAs a few solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are certainly many opinions as to what rules to follow, there are some standards that should always be adhered to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that a DBA will examine come from the master.sysperfinfo performance table. This table maintains a count of various statistics for the server and particular databases since the server was brought up. For servers that are kept up for long periods of time, these values can grow quite large and will impact how a particular ratio that a DBA might be looking at is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each SQL Server's individual 'personality' with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.
The following ratios are used on the Performance Analyst Home page to succinctly communicate the general overall performance levels of the monitored database:

- Data Cache Hit Ratio
- Procedure Plan Hit Ratio
- Large I/O Hit Rate
- Clean Buffer Grab Rate
- CPU Busy
- I/O Busy
- Server Idle

**Data Cache Hit Ratio**

Data read from memory produces user response times many times faster than when that same data is read from disk. The Sybase ASE data cache assists with keeping physical I/Os to an absolute minimum.

The data cache hit ratio is an excellent indicator of how often user requests for data are satisfied through memory as opposed to being physically read from disk. The table below describes the three key counters in Sybase ASE used to arrive at this statistic:

<table>
<thead>
<tr>
<th>Counter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL READS</td>
<td>Data read from memory for user requests.</td>
</tr>
<tr>
<td>PAGES PER I/O</td>
<td>The number of pages retrieved in a single I/O operation.</td>
</tr>
<tr>
<td>PHYSICAL READS</td>
<td>Data read physically from disk.</td>
</tr>
</tbody>
</table>
To help ensure excellent performance, keep your cache hit rate in the neighborhood of 90% or greater. Lower amounts can be okay for user ad hoc databases where sporadic, large table scan operations occur. However, anything below this general threshold for normal databases can require tuning attention, and the adjustment of the Sybase ASE memory tuning parameters. If you are using named caches, you can drill down into the cache hit rates for each named cache. This helps you understand which objects/operations are depressing the overall cache hit rate for the server.

If a problem is found in Sybase ASE servers, versions 11-12, you can increase the amount of the total memory configuration parameter or reduce the percentage of memory allocated to the procedure cache (by default, the data cache assumes any free memory left over after Sybase ASE has met its kernel and procedure cache needs). Take care when reducing the procedure cache, as this could reduce performance in the server as it relates to reading procedures in from disk. For Sybase ASE 12.5, the total memory configuration parameter can again be increased to provide more memory for the data cache (and any named caches), but in 12.5, if you want to reduce the size of the procedure cache, note that it is now configured in terms of literal size instead of a percentage of the overall configured memory.

Once the data cache has been adjusted, monitor Sybase ASE to see if the cache hit rate improves. If it does not, another increase may be necessary and examination of unnecessary large table scan operations. Also, keep a careful eye on the actual machine’s memory limits and swap activity. Increased swap activity can be indicative of too little memory left for the server machine.

Procedure Plan Hit Ratio

The Sybase ASE procedure cache is used to hold the definitions and query plans of stored procedures and triggers. It is used for short-term memory needs like statistics and query plans for parallel queries. When a user executes a stored procedure, Sybase ASE looks in the procedure cache for a query plan to use. If a query plan is available, Sybase ASE places it on the most recently used (MRU) end of the memory chain and the procedure begins to execute. If no execution plan is in memory, or if all copies of the plan are currently being used, the query tree for the procedure is read in again from the data dictionary, optimized, put on the MRU end of the chain, and executed. Note that other operations, like CREATE INDEX, can also use the procedure cache even when no procedure is referenced.

The more often that a procedure’s plan and definition can be referenced in memory, the better the procedure execution time.
A high procedure cache hit rate is a desirable thing. You should strive for a hit ratio between 95-100%, with 95% being a good performance benchmark for procedure code reference. Note that when a database is first started, the procedure cache hit rate is not at an optimal level because all code being used is relatively new, and as such, must be read in from disk and placed into the cache. If, however, after a solid hour or two of steady database time, the procedure cache hit rate has not increased to desirable levels, you should look into the possibility of increasing the amount of memory allocated to the cache. You can drill down into the procedure cache to view the procedures currently in memory along with how much memory they are consuming. If there is not enough memory to load a requested procedure, or the maximum number of compiled objects is already in use, Sybase ASE returns an error (normally a 701).

 Correction
If a problem is found in Sybase ASE servers, versions 11-12, you can increase the amount of the total memory configuration parameter or increase the percentage of memory allocated to the procedure cache (by default, the data cache assumes any free memory left over after Sybase ASE has met its kernel and procedure cache needs). You should be careful when increasing the procedure cache alone, as this could increase query response times due to more physical I/O being performed. For Sybase ASE 12.5, the total memory configuration parameter can again be increased to provide more memory for the Sybase ASE server, but in 12.5, if you want to increase the size of the procedure cache, note that it is now configured in terms of literal size instead of a percentage of the overall configured memory. Once the procedure cache has been adjusted, monitor Sybase ASE to see if the cache hit rate improves. If it does not, another increase may be necessary. Also, keep a careful eye on the actual machine’s memory limits and swap activity. Increased swap activity can be indicative of too little memory left for the server machine.

Large I/O Hit Rate

Large I/O can be enabled by splitting the default or any named cache into pools. By default, Sybase ASE performs I/O operations based on a 2-KB page size. For queries where pages are stored and accessed in a sequential manner, it is possible to read many more data pages in a single I/O operation. Large I/O can greatly reduce disk access time when the right situations exist. Operations that routinely perform large table scans, access image or text data, do bulk copies, scan the leaf level of nonclustered indexes, or initiate DBCC tasks can benefit from large I/O.

If large I/O has been configured and is being used, you should observe a high percentage of hits (the number of times large I/O could be performed vs. the number of times large I/O requests were denied by the server). If large I/O is not configured, no large I/O activity should be present.
As you might expect, if large I/O is in use, a high hit rate is desirable. You should strive for a hit ratio between 90-100%, with 90% being a good performance benchmark.

**Correction**
If large I/O is configured, but you see a low hit rate, you should configure more caches for large I/O use.

## Clean Buffer Grab Rate

As information is requested from users, buffers are moved into and out of the Sybase ASE data cache. Pages are also modified in the cache (termed dirty buffers) and need to be written out to disk. If Sybase ASE has to wait for a dirty buffer to be written out to disk before a requested buffer is placed into the cache, performance can suffer.

The clean buffer grab rate represents the percentage of time clean buffers were found and referenced in the cache as opposed to Sybase ASE finding dirty buffers.

**Metrics**
Ideally, the clean buffer grab rate should stay at or near 100%.

**Correction**
A poor clean buffer grab rate for either the default or named caches could indicate that the cache size is too small. You can look into adjusting the total memory configuration parameter higher. Monitor the actual machine’s memory limits and swap activity. Increased swap activity can be indicative of too little memory left for the server machine.

## CPU Busy

The CPU Busy statistic represents the percent of the sample interval during which the Adaptive Server was busy.
Correction

If you find that your CPU Busy value is consistently above 70%, consider adding additional hardware.

I/O Busy

This metric represents the number of clock ticks in the sample interval during which the user task performed I/O operations.

Correction

To improve throughput: Assign a higher priority to the application. Bind the application to a lightly loaded engine or engine group. Partition the application’s data onto multiple devices.

Server Idle

This metric represents the number of clock ticks in the sample interval during which the user task was idle.

Correction

To improve throughput:

- Assign a higher priority to the application.
- Bind the application to a lightly loaded engine or engine group.
- Partition the application’s data onto multiple devices.

Bottleneck Analysis Pane

When Sybase ASE Adaptive Server is running, every connected process is either busy doing work or waiting to work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. And this is where wait-based or bottleneck analysis comes into play. DBAs use this form of
performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps a DBA track where a database has been spending its time. If lock contention or heavy table scan activity has been dragging down database performance, a DBA can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, the DBA can drill down and oftentimes discover a fair amount of detail about which sessions and objects are causing the problem. The Performance Analyst Home page identifies the top system and session waits that might be currently a cause of lessened performance.

When using bottleneck analysis, a DBA cannot rely only on the information contained in the wait events that Sybase Adaptive Server provides. For example, a database might be suspect or offline. Such a failure will not be reflected in any wait event, but still represents a very real bottleneck to the database. In the same way that a DBA cannot depend on only a few ratios to properly carry out ratio-based performance analysis, an administrator must include other statistical metrics in their overall bottleneck analysis framework to obtain an accurate performance risk assessment. Performance Analyst works to identify bottlenecks in your database that fall outside of pure wait events so you can get a total picture of all stoppages in your system. The Performance Analyst Home page displays space-related bottlenecks as well as other sources of contention/bottlenecks that might be dragging down the overall performance of your system.

The following bottleneck indicators are used on the Performance Analyst Home page to succinctly communicate the general overall performance level of the monitored database:

- **Device I/O Contention**
- **Modify Conflicts**
- **Deadlocks**
- **Suspect Databases**
- **Databases Low on Space**
- **Logs Low on Space**
- **Tempdb Percent Full**
- **Task Context Switches**
- **Group Commit Sleeps**
- **Blocked Connections**

**Deadlocks**

A deadlock occurs when two processes have a lock on a separate page or object and each wants to acquire a lock on the other process’ page or object. Each waits for the
other to release the necessary lock. Sybase ASE constantly checks for deadlocks and, when found, chooses the transaction that has accumulated the least amount of CPU time and terminates the transaction. The server then rolls back that transaction and issues a notification of the event. The other process gets to move forward.

A deadlock occurs when two processes have a lock on a separate page or object and each wants to acquire a lock on the other process’ page or object. Each waits for the other to release the necessary lock. Sybase ASE constantly checks for deadlocks and, when found, chooses the transaction that has accumulated the least amount of CPU time and terminates it (the transaction). The server then rolls back that transaction and issues a notification of the event. The other process gets to move forward.

The deadlock statistic displays the number of current deadlocks in a Sybase ASE server.

**Location**  
Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Bottleneck Analysis Pane

**Metrics**  
A nonzero number should alert you to the fact that application conflicts are likely being experienced by your user community.

**Correction**  
Well-designed applications can minimize deadlocks by always acquiring locks in the same order. You should always do updates to multiple tables in the same order. Once Sybase ASE discovers a deadlock, it takes action and remedies the situation. Embarcadero Performance Analyst makes it easier to discover how prevalent deadlock activity is on a system; preventing deadlocks from occurring in the first place is more difficult. Those responsible for writing systems can minimize deadlocks by ensuring that applications acquire locks in the same order. Likewise, you should always do updates and other DML that act on multiple tables in the same order. You can also shrink the amount of time that Sybase ASE waits to check for deadlocks by modifying the deadlock checking period configuration parameter.

**Suspect Databases**

It can be hard to recover quickly from a suspect database. There are times when the cache of the database is suspect and not the actual database itself. If you stop and start the Sybase ASE server, you can verify if the cache is the culprit. If the database itself is damaged, there could be a true recovery situation.
Correction: The suspect database can be dropped using the DBCC DBREPAIR DROPDB command. You then need to re-create the database and perform a recovery operation using the most recent database dump.

Device I/O Contention

Device I/O Contention reflects the number of times a task or process was put to sleep while waiting for a semaphore for a particular database device.

When a task or process involves physical I/O, Sybase ASE first fills out the block I/O structure and links it to a per engine I/O queue. If two or more Sybase engines request an I/O structure from the same device at the exact same time, the server puts one of them to sleep where it waits for the semaphore it needs.

Correction: If consistent high numbers are viewed for Device I/O Contention, you can try redistributing the tables across devices (that are located on separate hard disks) or by adding devices (again, that are located on separate hard disks) and moving tables and indexes to them.

Modify Conflicts

For some database operations, Sybase ASE uses a specialized protection mechanism to get exclusive access to a page without using actual restrictive page locks. Examples include accessing certain system tables and dirty reads on data pages. These actions need exclusive access to the page in question, even though they do not actually modify it. Modify conflicts record how many times these actions conflicted with other processes that need true database locks.

Tempdb Percent Full

The Tempdb Percent Full statistic shows the percentage of the Tempdb that is full.

Metrics

Tempdb is probably the most important resource in Adaptive Server shared by all applications and processes. It is a server-wide resource used for internal processing tasks like work tables, sorts, reformatting, and index builds.

Correction
Problems can be identified by a consistently high percentage registering or receiving a message indicating that your transactions are being suspended until space is made available in the log. In the short term, try using the “dump tran” DBCC command. If you suspect your application requires a very large tempdb, it should be placed on small fast disks. These disks should have no other data on them.

**Note:** On some systems, tempdb performs much faster using an operating system file rather than raw devices. This is because an operating system file uses buffering, which is faster than direct writes to a raw device.

## Task Context Switches

Task Context Switches summarizes task-switch activity for all engines on SMP servers. You can use this statistic to observe the effect of reconfigurations.

**Location** Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Bottleneck Analysis Pane Sybase ASE Performance Analyst Statistics > Databases (Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics** You might reconfigure a cache or add memory if tasks appear to block on cache search misses and to be switched out often. Then, check the data to see if tasks tend to be switched out more or less often.

## Group Commit Sleeps

For databases needing high throughput, a large log I/O size is very important to prevent disk queuing problems on the transaction log. Group commit sleeps reflect the number of times a task performed a transactional commit operation and was put to sleep by the server until data in the log was written to disk.

**Location** Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Bottleneck Analysis Pane Sybase ASE Performance Analyst Statistics > I/O (Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics** You should examine group commit sleeps in conjunction with the number of committed transactions (found on the Users performance category view).

**Correction** A high count for group commit sleeps is not necessarily a problem if the server’s transaction rate is low. If there are a significant number of transactions that result in group commit sleeps, and the log I/O size is greater than 2 KB, a smaller log I/O size can help to reduce commit time by causing more frequent page flushes. Other factors that can affect group commit sleeps are the size of the server run queue and the speed of the hard disk where the log is located.

## Blocked Connections

A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches on large systems. Although Sybase ASE supports flexible locking mechanisms, blocking lock situations do crop up. Blocks are
most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency.

The blocked statistic displays the number of current processes blocked by other processes.

**Location** Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Bottleneck Analysis Pane

**Metrics** While the lock contention rate is a better measure of the overall lock contention situation, if you consistently see positive numbers for the blocked statistic there may be a bottleneck for some processes. You can easily drill down and discover the exact process(es) holding locks that are blocking out other user activity.

**Correction** Once you discover a blocking lock situation, you can normally remedy it by issuing a KILL against the offending process. This eliminates the user’s stranglehold on the objects the user was accessing, and usually results in other user processes completing in an instant. Discovering the blocked lock situation is made easier by using tools like Performance Analyst, but preventing the blocking lock situation in the first place is tricky. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is an art. The key to avoiding lock contention is to process user transactions in the quickest and most efficient manner possible - something not always easy to do. By default, all processes wait indefinitely for locks in Sybase ASE. You can change this behavior by modifying the lock wait period configuration parameter, which limits the number of seconds that a process waits for a lock before timing out.

**Databases Low on Space**

The Databases Low on Space statistic indicates if any databases in the server are approaching low levels of available free space. Although good to know, you need a more detailed listing by database to determine where any actual space shortages exist in the server.
If any one database begins to approach 90% used space, and is continuing to dynamically grow, you should take action to prevent any future space allocation errors.

Correction
If a database is approaching its limit on space, you can either extend the database onto a new device, or if space exists on the device where the database currently resides, you can allocate more space for the database on the current device.

Logs Low on Space

This statistic indicates if any log for a database in the Sybase ASE server is approaching low levels of available free space. Although good to know, a more detailed listing by database is needed to determine where any actual space shortages exist in the server.

Correction
If a database log consistently approaches its limit on used space, there are a few actions a DBA can take to prevent a database from freezing. A backup (dump) of the log can be taken: If log backups are not required for disaster recovery, the truncate log on checkpoint option can be set for the database. Setting this option deletes any space devoted to transactions in the log that have already completed when a database checkpoint occurs. You can extend the log onto a new device. Or, if space exists on the device on which the database log currently resides, you can allocate more space for the log on the current device.

I/O Analysis Pane

I/O statistics gives you a succinct overview of the datasource’s overall performance. The ratios on the Home page are:

- Server Reads
- Server Writes
- Transaction Log Writes
- I/O Errors
Server Reads
Total Server Reads reflect the total number of physical reads performed by the database server since the last refresh.

Location: Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > I/O Analysis Pane

Metrics: Large numbers of physical reads could reflect a too small data or procedure cache. You should examine the data and procedure cache hit rates to determine the overall effectiveness of logical vs. physical I/O.

Server Writes
This value reflects the total number of physical writes performed by the database server since the last refresh.

Location: Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > I/O Analysis Pane

Transaction Log Writes
Transaction Log Writes refers to the number of times Sybase ASE wrote a transaction log page to disk since the last refresh. When the current log page becomes full, Sybase ASE writes it out to disk. Sybase ASE also writes transaction log pages to disk after a transaction commits.

Location: Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > I/O Analysis Pane

I/O Errors
The I/O Errors value reflects total number of I/O errors (errors during read and write operations) encountered by the database server since the last refresh.

Location: Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > I/O Analysis Pane

Storage Analysis Pane
While DBAs focus on memory settings and tuning SQL, they frequently forget how dangerous and insidious storage problems can be. This is not a good mindset because storage headaches can play a major role in wrecking an otherwise well-running database.

Storage problems generally take one of two forms:

- The ‘hit-the-wall’ variety that can bring things to a complete standstill.
Storage problems have the capability to bring the curtain down on a database very quickly, as in the case of a transaction log running out of free space. But storage problems can also silently work behind the scenes to slowly, but surely rob a database of its performance. For example, a hub table in a busy database might be accessed very quickly when an application is first given life, but over time, if it develops a heavy forwarded row problem, it can cause things to run very differently.

The Storage Analysis section of the Performance Analyst Home page displays the Total Used and Free Space of all tablespaces in the database. It also provides a count of the number of databases, files, and file groups that exist on the server. For more detailed information on database space, you can use the Performance Analyst Space home page or the Space Detail.

The following ratios succinctly communicate the general overall performance levels of the datasource:

- **Total Used**
- **Total Free**
- **Number of Databases**
- **Number of Devices**

### Total Used

The Total Used statistic shows the total amount of space currently in use by the Sybase ASE Server.

**Location** [Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Storage Analysis Pane](#)

### Total Free

The Total Free statistic shows the total amount of free space available to the Sybase ASE Server.

**Location** [Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Storage Analysis Pane](#)

### Correction

A low percentage of free space indicates that additional space should be allocated to your database(s)/devices.

### Number of Databases

This value indicates the total number of database currently defined on the Sybase ASE server.
Number of Devices

This value indicates the total number of devices currently defined on the Sybase ASE server.

Workload Analysis Pane

When your phone starts ringing with complaints of performance slowdowns, some of the first questions you should answer are:

- Who is currently connected to the database?
- What resources are they using?
- What are they currently executing?

The Workload Analysis section of the Performance Analyst Home page provides insight into the leading resource hogs of a server, as well as a count of total active and inactive processes.

Workload Analysis statistics include:

- Top I/O Process
- Top Memory Process
- Top CPU Process
- Active Processes
- Inactive Processes

Top I/O Process

The Top I/O Process statistic identifies the current SPID with the highest percentage of I/O activity.
Location  Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Workload Analysis Pane

Metrics  If any one session uses more than 50% of a total resource (CPU, memory, etc.) drill-down into the session to investigate what work is currently executing.

Top Memory Process
The Top Memory Process statistic identifies the current SPID with the highest percentage of memory consumption.

Location  Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Workload Analysis Pane

Metrics  If any one session uses more than 50% of a total resource (CPU, memory, etc.) drill-down into the session to investigate what work is currently executing.

Top CPU Process
The Top CPU Process statistic identifies the current SPID with the highest percentage of CPU consumption.

Location  Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Workload Analysis Pane

Metrics  If any one session uses more than 50% of a total resource (CPU, memory, etc.) drill-down into the session to investigate what work is currently executing.

Active Processes
The Active Processes statistic is the total number of active and open threads reported on the Server. Active Processes displays the number of processes actively performing work.

Location  Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Workload Analysis Pane

Inactive Processes
The Inactive Sessions statistic represents the total number of threads logged onto the server that are currently idle.
Location  Sybase ASE Performance Analyst Statistics > Home View (DBArtisan - Sybase ASE Performance Analyst) > Workload Analysis Pane

Metrics  A large number of inactive processes could indicate user sessions that have mistakenly been left logged on. Since each user thread consumes a portion of memory on the server, to reduce resource usage, you should sever any sessions that do not need a connection.

Correction  Drill down into the Session Waits page and check sessions that have many seconds idle and/or that have been logged on for very long periods of time, as indicated by the logon time column. After verifying that a session is no longer necessary, you can KILL it.
Memory View (Sybase ASE Performance Analyst)

In addition to a Home page, the Memory category of Sybase ASE Performance Analyst includes the following tabbed pages:

- Data Cache Tab
- Procedure Cache Tab

Home

The Memory performance category view displays the following vital Sybase ASE memory statistics:

- Key Ratio Analysis Pane
- Bottleneck Analysis Pane
- Metadata Cache Ratio Analysis Pane
- Memory Analysis Pane
- Workload Analysis Pane

Key Ratio Analysis Pane

Database performance analysts typically use one of two methods for examining the performance levels of a database - ratio-based or wait/bottleneck-based. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for busy DBA’s to use for at-a-glance performance analysis. Many DBAs have large database farms to contend with and cannot spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving DBAs a few solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are certainly many opinions as to what rules to follow, there are some standards that should always be adhered to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that a DBA will examine come from the master.sysperfinfo performance table. This table maintains a count of various statistics for the server and particular databases since the server was brought up. For servers that are kept up for long periods of time, these values can grow quite large and will impact how a particular ratio that a DBA might be looking at is interpreted. However, if delta statistics are used (taking, for a specified sampling period, the before and after counts of...
each statistic that make up a ratio), then an accurate and current portrayal of the various ratios can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each SQL Server's individual 'personality' with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following memory ratios are used on the Performance Analyst Home page to succinctly communicate the general overall memory performance levels of the monitored database:

- Dirty Read Restarts
- Dirty Read Requests
- Procedure Requests
- Procedure Reads from Disk

The following statistics, available on this pane, are duplicates of statistics appearing on the Key Ratio Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- Data Cache Hit Ratio
- Procedure Plan Hit Ratio
- Large I/O Hit Rate
- Clean Buffer Grab Rate

**Dirty Read Restarts**

Sybase ASE allows dirty reads, which are reads of uncommitted data. To accomplish a dirty read, Sybase ASE uses a special lightweight protection mechanism to gain access to an object without using actual page locks. A dirty read restart occurs when a dirty read is active on an object page, and another process makes changes to the page that cause the page to be deallocated in memory. The scan for the dirty read must be restarted. The amount shown for dirty read restarts are the number of restarts that occurred since the last Embarcadero Performance Analyst refresh.
Values observed much above zero should serve as a signal that application modifications can be in order. Most applications should do everything possible to avoid restarts because of the large overhead they incur.

Correction
If the numbers observed for dirty read restarts are significant, you can want to look into modifying applications that use dirty reads to accomplish data acquisition.

Dirty Read Requests
Sybase ASE allows dirty reads, which are reads of uncommitted data. To accomplish a dirty read, Sybase ASE uses a special lightweight protection mechanism to gain access to an object without using actual page locks. This statistic displays the number of dirty reads that occurred since the last refresh in Embarcadero Performance Analyst.

Procedure Requests
The Procedure Requests statistic reports the number of times that stored procedures were executed since Embarcadero Performance Analyst was last refreshed. Such a request could use either an unused copy of the procedure’s query plan in memory or if no such copy exists, the procedure must be read in from disk.

Procedure Reads from Disk
The Procedure Reads from Disk statistic reports the number of times since Embarcadero Performance Analyst was last refreshed that stored procedures were read from disk rather than copied in the procedure cache.
Memory View (Sybase ASE Performance Analyst)

Location  Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Home > Key Ratio Analysis Pane

Metrics  You should examine this number in conjunction with the overall procedure cache hit rate. Observing large numbers in this statistic indicates a lower than ideal procedure cache hit rate. Note that when a database is first started, this statistic is likely larger than desired because all code being used is relatively new and as such, must be read in from disk and placed into the cache. If, however, after a solid hour or two of steady database time, the procedure cache hit rate has not increased to desirable levels and this statistic continues to sport high numbers, you should look into the possibility of increasing the amount of memory allocated to the cache.

Correction  If a problem is found in Sybase ASE servers, versions 11-12, you can increase the amount of the total memory configuration parameter and/or increase the percentage of memory allocated to the procedure cache (by default, the data cache assumes any free memory left over after Sybase ASE has met its kernel and procedure cache needs). Take care when increasing the procedure cache alone, as this could increase query response times due to more physical I/O being performed. For Sybase ASE 12.5, the total memory configuration parameter can again be increased to provide more memory for the Sybase ASE server, but in 12.5, if you want to increase the size of the procedure cache, note that it is now configured in terms of literal size instead of a percentage of the overall configured memory. Once the procedure cache has been adjusted, monitor Sybase ASE to see if the cache hit rate improves. If it does not, another increase may be necessary. Also, keep a careful eye on the actual machine’s memory limits and swap activity. Increased swap activity can be indicative of too little memory left for the server machine.

Bottleneck Analysis Pane

When Sybase Adaptive Server is running, every connected process is either busy doing work or waiting to work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. And this is where wait-based or bottleneck analysis comes into play. DBAs use this form of performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Bottleneck analysis is a valid method of measuring performance because it helps a DBA track where a database has been spending its time. If lock contention or heavy table scan activity has been dragging down database performance, a DBA can use bottleneck analysis to confirm the actual root cause. Once one or more wait events or other bottlenecks have been pinpointed as possible performance vampires, the DBA can drill down and oftentimes discover a fair amount of detail about which sessions and objects are causing the problem.

Memory bottlenecks can definitely cause performance degradation in an otherwise well-running database. Typically, these bottlenecks center around the server latches, which are lightweight locks used to protect certain resources in memory. To help you identify such problems, the following statistics are presented on the Performance Analyst Memory home page:

- Log Semaphore Contention
Log Semaphore Contention

The Log Semaphore Contention statistic measures the total number of times tasks requested a log semaphore. This includes those granted immediately and those for which the task had to wait.

Location Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics In high throughput environments with a large number of concurrent users committing transactions, you should expect a certain amount of contention for the log semaphore.

Latch Contention

The Latch Contention statistic reports the number of times a task was switched out because it needed to wait for a latch. If your user tables use only allpages-locking, this latch contention is taking place either on a data-only-locked system table or on allocation pages. If your applications use data-only-locking, the contention reported here includes all waits for latches, including those on index pages and OAM pages as well as allocation pages.
In SMP environments where inserts and expanding updates are extremely high, so that page allocations take place very frequently, contention for the allocation page latch can reduce performance. Normally, Adaptive Server allocates new pages for an object on an allocation unit that is already in use by the object and known to have free space. For each object, Adaptive Server tracks this allocation page number as a hint for any tasks that need to allocate a page for that object. When more than one task at a time needs to allocate a page on the same allocation unit, the second and subsequent tasks block on the latch on the allocation page.

**Correction**
You can specify a "greedy allocation" scheme, so that Adaptive Server keeps a list of eight allocation hints for page allocations for a table. The effect of `dbcc tune(des_greedyalloc)` are not persistent, so you need to reissue the commands after a reboot. You should use this command only if all of the following are true: You have multiple engines. It is rarely useful with fewer than four engines. A large number of pages are being allocated for the object. You can use `sp_spaceused` or `optdiag` to track the number of pages. The latch contention counter shows contention.

### Waits on Execution Plans

The Waits on Execution Plans value represents the number of times that a process attempting to use `sp_showplan` had to wait to acquire read access to the query plan.

**Location**
Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**
Query plans may be unavailable if you run `sp_showplan` before the compiled plan is completed or after the query plan finished executing. In these cases, Sybase ASE tries to access the plan three times and then returns a message to the user.

### Large I/Os Denied

The Large I/Os Denied statistic represents the number of times that large I/O could not be performed.
Metrics
Adaptive Server cannot perform large I/O for the following reasons: If any page in a buffer already resides in another pool. When there are no buffers available in the requested pool. On the first extent of an allocation unit, since it contains the allocation page, which is always read into the 2K pool.

Correction
If a high percentage of large I/Os were denied, it indicates that using larger pools might not be as effective as it could be. If a cache contains a large I/O pool, and queries perform both 2K and 16K I/O on the same objects, there will always be some percentage of large I/Os that cannot be performed because pages are in the 2K pool.

If more than half of the large I/Os were denied, and you are using 16K I/O, try moving all of the space from the 16K pool to the 8K pool. Re-run the test to see if total I/O is reduced. Note that when a 16K I/O is denied, Adaptive Server does not check for 8K or 4K pools, but uses the 2K pool.

Buffers Grabbed Dirty
The Buffers Grabbed Dirty statistic represents the number of times Sybase ASE found dirty buffers since the last refresh in Embarcadero Performance Analyst.

As users request information, buffers are moved into and out of the Sybase ASE data cache. Pages are also modified in the cache (termed dirty buffers) and need to be written out to disk. If Sybase ASE has to wait for a dirty buffer to be written out to disk before a requested buffer is placed into the cache, performance can suffer.

Correction
Seeing high numbers for this statistic could indicate that the cache size is too small. You should look into carefully adjusting the total memory configuration parameter to be higher. However, keep a careful eye on the actual machine’s memory limits and swap activity. Increased swap activity can indicate too little memory left for the server machine.

Procedure Removals
The Procedure Removals statistic reports the number of times that stored procedures were aged out of the procedure cache since Embarcadero Performance Analyst was last refreshed.
Location  Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  High numbers, along with a lower than desired procedure cache hit rate, could indicate a procedure cache that is too small.

Correction  If a problem is found in Sybase ASE servers, versions 11-12, you can increase the amount of the total memory configuration parameter and/or increase the percentage of memory allocated to the procedure cache (by default, the data cache assumes any free memory left over after Sybase ASE has met its kernel and procedure cache needs). Take care when increasing the procedure cache only, as this could increase query response times due to more physical I/O being performed. For Sybase ASE 12.5, the total memory configuration parameter can again be increased to provide more memory for the Sybase ASE server, but in 12.5, if you wish to increase the size of the procedure cache, note that it is now configured in terms of literal size instead of a percentage of the overall configured memory. Once the procedure cache has been adjusted, monitor Sybase ASE to see if the cache hit rate improves. If it does not, another increase may be necessary. Also, keep a careful eye on the actual machine's memory limits and swap activity. Increased swap activity can indicate too little memory left for the server machine.

Metadata Cache Ratio Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE Memory Home Page to succinctly communicate the general overall performance levels of the memory structures:

- Open Objects
- Open Indexes
- Open Databases
- Object Spinlock Contention
- Index Spinlock Contention
- Hash Spinlock Contention

Open Objects

The Open Objects statistic represents the use of the Adaptive Server metadata cache for open objects. The statistic includes number of active objects, free objects, and the maximum number of objects used.
Open Indexes

The Open Indexes statistic represents the use of the Adaptive Server metadata cache for open indexes. The statistic includes the number of active indexes, free indexes, and the maximum number of indexes.

Correction You can use this information to set the configuration parameter’s number of open indexes.

Open Databases

The Open Databases statistic shows the use of the Adaptive Server metadata cache for open databases. This statistic charts the number of active databases, free databases, and the maximum number of databases used.

When Adaptive Server opens a database, it has to access information about it in the respective system table: sysdatabases. The metadata cache for databases lets Adaptive Server access the information that describes it in the sysdatabases row directly in its in-memory structure. This improves performance because it allows the Adaptive Server to bypass expensive calls that require disk access. It also reduces synchronization and spinlock contention when Adaptive Server has to retrieve database information at runtime.
Metrics
Managing individual metadata caches for databases, indexes, or objects is beneficial for a database that contains a large number of indexes and objects, and where there is high concurrency among users.

Correction You can use this information to set the configuration parameter’s number of open databases.

**Object Spinlock Contention**

The Object Spinlock Contention statistic represents spinlock contention on the object descriptor caches.

Correction You can use this information to tune the configuration parameter’s open object spinlock and open index spinlock ratios. If the reported contention is more than 3%, decrease the value of the corresponding parameter to lower the number of objects or indexes that are protected by a single spinlock.

**Index Spinlock Contention**

The Index Spinlock Contention value represents spinlock contention on the index descriptor caches.

Correction You can use this information to tune the configuration parameter’s open object spinlock and open index spinlock ratios. If the reported contention is more than 3%, decrease the value of the corresponding parameter to lower the number of objects or indexes that are protected by a single spinlock.

**Hash Spinlock Contention**

This metric represents the contention for the spinlock on the index metadata cache hash table.
Memory View (Sybase ASE Performance Analyst)

Correction You can use this information to tune the open index hash spinlock ratio configuration parameter. If the reported contention is greater than 3%, decrease the value of the parameter.

Memory Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE Memory Home Page to succinctly communicate the general overall performance levels of the memory structures:

- Buffer Cache
- Procedure Cache
- Connection Memory
- Open Database Memory
- Open Object Memory
- Open Index Memory

Buffer Cache

The Buffer Cache statistic displays the amount of memory currently allocated to the Buffer Cache.

Procedure Cache

The Procedure Cache value displays the amount of memory currently allocated to the procedure cache.

Connection Memory

The Connection Memory value indicates the amount of memory currently allocated to user connections.
Memory View (Sybase ASE Performance Analyst)

Location Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Home > Memory Analysis Pane

Metrics Each connection requires approximately 60 KB.

Open Database Memory

The Open Database Memory value represents the current amount of memory allocated in the number of open databases parameter.

Location Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Home > Memory Analysis Pane

Open Object Memory

This value represents the current amount of memory allocated in the number of open objects parameter.

Location Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Home > Memory Analysis Pane

Open Index Memory

This value represents the current amount of memory allocated in the number of open indexes parameter.

Location Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Home > Memory Analysis Pane

Workload Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE Memory Home Page to succinctly communicate the general overall performance levels of the memory structures:

- Top Memory Hogs

Top Memory Hogs

This metric identifies the process that currently is using the highest percentage of memory in the database.
Metrics

It is not uncommon for one or two users to cause the majority of runtime problems that plague a server. The problem could be a runaway process, an untuned batch procedure, or other user-initiated operation. If your database server does not have an overabundance of memory, then you should periodically check to see who your heavy memory users are along with the total percentage of memory each takes up. If you see one or two users who have more than 25-50% of the total memory usage, then you should further investigate the sessions to see what activities they are performing.

Data Cache Tab

The Data Cache tab of the Memory Detail View includes the following sections:

- Cache Configurations
- Cache Efficiency
- Cached Objects
- Cache I/O Activity

The following statistic, available on this tab, duplicates a statistic available on the Key Ratio Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- Data Cache Hit Ratio

Cache Configurations

The Cache Configuration view represents the default and named data caches and the memory configuration in MB.

Cache Efficiency

The Cache Efficiency section summarizes behavior for the default data cache and all named data caches combined. The table below describes the information available on the Cache Efficiency detail view:
Memory View (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache Name</td>
<td>The name of the specified cache</td>
</tr>
<tr>
<td>Hit Rate</td>
<td>The percentage of cache hits compared to the total number of cache searches.</td>
</tr>
<tr>
<td>Percent Used</td>
<td>The percentage of searches using this cache as a percentage of searches across all caches.</td>
</tr>
<tr>
<td>Spinlocks</td>
<td>The number of spinlocks.</td>
</tr>
<tr>
<td>LRU Buffers</td>
<td>The number of buffers that were retrieved and replaced in the Least Recently Used section of the pool.</td>
</tr>
<tr>
<td>MRU Buffers</td>
<td>The number of buffers that were retrieved and replaced in the Most Recently Used section of the pool.</td>
</tr>
<tr>
<td>Large I/Os</td>
<td>The size (bytes) of the I/O buffer for the pool.</td>
</tr>
<tr>
<td>Dirty Reads</td>
<td>The number of dirty reads.</td>
</tr>
</tbody>
</table>

Location  Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Data Cache Tab

Metrics Interpreting cache hit data requires an understanding of how the application uses each cache. In caches that are created to hold specific objects such as indexes or look up tables, cache hit ratios can reach 100%. In caches used for random point queries on huge tables, cache hit ratios can be quite low but still represent effective cache use. This data can also help you determine if adding more memory would improve performance. For example, if "Cache Hits" is high, adding memory probably would not help much.

Correction You can compare the "percent used" value for each cache to determine if there are caches that are over- or under-utilized. If you decide that a cache is not well utilized, you can: Change the cache bindings to balance utilization. Resize the cache to correspond more appropriately to its utilization.

Cached Objects

The Cached Objects section shows the objects that are currently cached. The table below describes the information available on the Cached Objects detail view:
### Column | Description
--- | ---
Cache Name | The name of the specified cache.
Database Name | The name of the database where the object resides.
Object Owner | The owner of the object.
Object Name | The name of the object.
Object Type | The type of the object.
Cached (KB) | The amount, in Kilobytes, of the cached object.
Processes Accessing | The number of processes accessing the specified object.

Location [Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Data Cache Tab](#)

### Cache I/O Activity

The Cache I/O Activity view shows how many searches were directed to each cache. The table below describes the information available on the Cache I/O Activity view:
## Memory View (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache Name</td>
<td>The name of the specified cache.</td>
</tr>
<tr>
<td>Physical Reads</td>
<td>The number of physical reads associated with the specified cache.</td>
</tr>
<tr>
<td>Pages Touched</td>
<td>The number of pages touched by the cache.</td>
</tr>
<tr>
<td>Pages Read</td>
<td>The number of pages read by the cache.</td>
</tr>
<tr>
<td>Buffers to MRU</td>
<td>The number of buffers that were retrieved and replaced in the Most Recently Used section of the pool.</td>
</tr>
<tr>

<td>The number of buffers that were retrieved and replaced in the Least Recently Used section of the pool.</td>
</tr>
<tr>
<td>I/O Buffer Size</td>
<td>The size (bytes) of the I/O buffer for the pool.</td>
</tr>
<tr>
<td>Allocated (KB)</td>
<td>The number of KB that have been allocated for the pool.</td>
</tr>
<tr>
<td>Stalls</td>
<td>The number of times a process had to wait for a free procedure cache buffer when installing a stored procedure into cache.</td>
</tr>
</tbody>
</table>

**Location**  Sybase ASE Performance Analyst Statistics > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Data Cache Tab

**Metrics**  You can compare the values in this view for each cache to determine if there are caches that are over- or under-utilized.

**Correction**  If you determine that a cache is not used as well as you would like, you can: Change which objects are bound to each cache to balance use. Resize the cache to correspond more appropriately to its use.

## Procedure Cache Tab

The Procedure Cache tab of the Memory Detail View includes the following sections:

- Procedure Cache Activity
- Procedure Cache Detail
- Current Procedure Usage

The following statistic, available on this tab, duplicates a statistic available on the Key Ratio Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- Procedure Plan Hit Ratio
Procedure Cache Activity

The Procedure Cache Activity view summarizes the key metrics concerning the Procedure Cache. The table below describes the information available on the Procedure Cache Activity view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requests</td>
<td>The number of stored procedures requested from the cache.</td>
</tr>
<tr>
<td>Loads</td>
<td>The number of stored procedures loaded into cache.</td>
</tr>
<tr>
<td>Writes</td>
<td>The number of times a stored procedure was normalized and the tree was written back to sysprocedures. This happens when a stored procedure (or trigger) is created during the interval between polls. A degradation in performance can occur if an application program generates stored procedures.</td>
</tr>
<tr>
<td>Stalls</td>
<td>The number of times a process had to wait for a free procedure cache buffer when installing a stored procedure into cache.</td>
</tr>
</tbody>
</table>

Location [Sybase ASE Performance Analyst Statistics](/SybaseASEPerformanceAnalystStatistics) > [Memory View (DBArtisan - Sybase ASE Performance Analyst)](/MemoryViewDBArtisanSybaseASEPerformanceAnalyst) > [Procedure Cache Tab](/ProcedureCacheTab)

Procedure Cache Detail

The Procedure Cache Detail view summarizes the key metrics concerning the Procedure Cache. The table below describes the information available on the Procedure Cache Detail view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Name</td>
<td>The name of the object.</td>
</tr>
<tr>
<td>Object Owner</td>
<td>The object’s owner.</td>
</tr>
<tr>
<td>Object Type</td>
<td>The type of object.</td>

<td>The amount of memory the procedure used in kilobytes.</td>
</tr>
<tr>
<td>Program Name</td>
<td>The name of the program where the procedure is used.</td>
</tr>
</tbody>
</table>

Location [Sybase ASE Performance Analyst Statistics](#) > Memory View (DBArtisan - Sybase ASE Performance Analyst) > Procedure Cache Tab
I/O (Sybase ASE Performance Analyst)

In addition to a Home page, the I/O category of Sybase ASE Performance Analyst includes the following tabbed pages:

- Databases tab
- Devices tab
- Engines Tab
- Network tab
- Objects tab

Home

The I/O performance category page displays the following vital Sybase ASE I/O statistics:

- Bottleneck Analysis Pane
- Key System Analysis Pane
- Network Analysis Pane
- Transaction Log Analysis Pane
- Workload Analysis Pane

Key System Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE I/O Home Page to succinctly communicate the general overall performance levels of I/O:

- Physical Reads
- APF Reads
- Physical Writes
- Procedure Requests from Disk
- Data Cache Searches
- Checkpoints
- Large I/Os Performed
Physical Reads

Physical Reads represents the total number of physical reads performed by the database server since the last refresh.

Metrics Large numbers of physical reads could reflect a too small data or procedure cache. You should examine the data and procedure cache hit rates to determine the overall effectiveness of logical vs. physical I/O.

APF Reads

This metric represents the number of pages that were read by asynchronous prefetch since the last refresh.

Metrics Asynchronous prefetch tries to find a page it needs to read in the data cache using a quick scan without holding the cache spinlock. If that does not succeed, it then performs a thorough scan holding the spinlock.

Physical Writes

This value reflects total number of physical writes performed by the database server since the last refresh.

Procedure Requests from Disk

The Procedure Requests from Disk value represents the number of times that stored procedures were read from disk rather than found and copied in the procedure cache.
Metrics If you see a relatively high number, it could indicate that the procedure cache is too small.

Correction You should increase the size of the memory allocated to the procedure cache memory structure.

**Data Cache Searches**

The Data Cache Searches value represents the number of times that a needed page was found in any cache.

Correction If you see a high number of cache misses, you should investigate statistics for each cache.

**Checkpoints**

The Checkpoints value represents the combined number of normal and free checkpoints that occurred during the sample interval.

Metrics Checkpoints write dirty pages (pages that have been modified in memory, but not written to disk) to the database device. Adaptive Server's automatic (normal) checkpoint mechanism works to maintain a minimum recovery interval. By tracking the number of log records in the transaction log since the last checkpoint was performed, it estimates whether the time required to recover the transactions exceeds the recovery interval. If so, the checkpoint process scans all data caches and writes out all changed data pages. When Adaptive Server has no user tasks to process, a housekeeper task begins writing dirty buffers to disk. These writes are done during the server's idle cycles, so they are known as "free writes." They result in improved CPU use and a decreased need for buffer washing during transaction processing. If the housekeeper process finishes writing all dirty pages in all caches to disk, it checks the number of rows in the transaction log since the last checkpoint. If there are more than 100 log records, it issues a checkpoint. This is called a "free checkpoint" because it requires very little overhead. In addition, it reduces future overhead for normal checkpoints.

**Large I/Os Performed**

The Large I/Os Performed statistic measures the number of times that a requested large I/O was performed.
Adaptive Server cannot perform large I/O for the following situations:

- If any page in a buffer already resides in another pool.
- When there are no buffers available in the requested pool.
- On the first extent of an allocation unit, since it contains the allocation page, which is always read into the 2K pool.

Correction

- If a high percentage of large I/Os were denied, it indicates that the use of the larger pools might not be as effective as it could be. If a cache contains a large I/O pool, and queries perform both 2K and 16K I/O on the same objects, there will always be some percentage of large I/Os that cannot be performed because pages are in the 2K pool.
- If more than half of the large I/Os were denied, and you are using 16K I/O, try moving all of the space from the 16K pool to the 8K pool. Re-run the test to see if total I/O is reduced. Note that when a 16K I/O is denied, Adaptive Server does not check for 8K or 4K pools, but uses the 2K pool.

Bottleneck Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE I/O Home Page to succinctly communicate the general overall performance levels of I/O:

- Delayed Disk IOs
- Outstanding Disk I/Os
- Disk I/O Structure Contention
- Total I/O
- I/O Errors
- Hottest Devices

The following statistic, available on this pane, duplicates a statistic available on the Key Ratio Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- I/O Busy

The following statistics, available on this pane, are duplicates of statistics available on the Bottleneck Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- Group Commit Sleeps

Delayed Disk IOs

The Delayed Disk IOs value is the number of I/Os delayed when the limit on disk I/O structures is reached.
I/O (Sybase ASE Performance Analyst)

Location  Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  When Adaptive Server exceeds the number of available disk I/O control blocks, I/O is delayed because Adaptive Server requires that tasks get a disk I/O control block before initiating an I/O request.

Correction  If you see a nonzero value for delayed disk I/Os, try to add to the number of available disk I/O control blocks by increasing the configuration parameter.

Outstanding Disk I/Os

The Outstanding Disk I/Os statistic reflects the maximum number of I/Os pending for Sybase ASE since the last refresh.

Location  Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  If you see nonzero numbers for both outstanding and delayed disk I/Os, there could be a problem in many areas.

Disk I/O Structure Contention

When a Sybase ASE server begins to experience I/O delays, the result can be a very dissatisfied user community. When such problems begin to occur, you should investigate Sybase ASE or operating system limits. It could be that I/O operations are being blocked by one or both.

The Disk I/O Structures statistic represents the number of I/O delays caused by Sybase ASE reaching the limit on disk I/O structures. When Sybase ASE exceeds the number of available disk I/O control blocks, I/O is deferred because Sybase ASE requires that any task get a disk I/O control block before beginning an I/O request.

Location  Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Consistent numbers above zero should be a cause for concern.

Correction  If you continue to see nonzero numbers for this statistic, you can try increasing the number of available disk I/O control blocks by increasing the configuration parameter disk I/O structures.

Total I/O

The Total I/O statistic represents the total number of physical reads and writes.
I/O (Sybase ASE Performance Analyst)

Location Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

I/O Errors

I/O error rate reflects total number of I/O errors (errors during read and write operations) encountered by the server since the last refresh inside Performance Analyst. The I/O errors rate is a percentage based on Total I/O (the sum of the physical reads and writes).

Metrics You should observe few, if any errors.

Correction If you notice any errors, you should check the Sybase ASE error log for details.

I/O Busy

This metric represents the number of clock ticks in the sample interval during which the user task performed I/O operations.

Metrics High numbers indicate an I/O-intensive process. If idle time is also high, the application could be I/O bound.

Correction The application might achieve better throughput if you assign it a higher priority, bind it to a lightly loaded engine or engine group, or partition the application's data onto multiple devices.

Hottest Devices

The Hottest Devices view identifies the configured devices engaged in the most I/O activity. In Sybase ASE, when a task or process needs to perform physical I/O, the server fills out the actual block I/O structure and links it to a per-engine I/O queue. If two Sybase ASE engines request the same I/O structure from the exact same device at the identical time, one of them is put to sleep by the server and it waits for the semaphore it needs.

Device I/O Contention reflects the number of times a task or process was put to sleep while waiting for a semaphore for a particular database device.

The table below describes the information available on the Hottest Devices view:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device Name</td>
<td>The name of the device.</td>
</tr>
<tr>
<td>APF Reads</td>
<td>The number of asynchronous pre-fetch buffers read.</td>
</tr>
<tr>
<td>Physical Reads</td>
<td>The total number of physical reads performed by the database server since the last refresh</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>The total number of physical writes performed by the database server since the last refresh</td>
</tr>
<tr>
<td>Total I/O</td>
<td>The combined total of read and write operations.</td>
</tr>
</tbody>
</table>

**Location**  
Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

**Correction**  
If you consistently see high numbers for Device I/O Contention, you can try redistributing the tables across devices (that are located on separate hard disks) or by adding devices (again, that are located on separate hard disks) and moving tables and indexes to them.

**Network Analysis Pane**

The following statistics are used on the Performance Analyst for Sybase ASE I/O page to succinctly communicate the general overall performance levels of I/O:

- **Packets Sent**
- **Packets Received**
- **Network Delays**
- **Network Errors**

**Packets Sent**

Packets Sent displays the number of times Sybase ASE sent a packet to a client application.

**Location**  
Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Network Analysis Pane

**Packets Received**

Total Packets Received reflects the number of times Sybase ASE received a packet from a client application.
Network Delays

The Sybase ASE server normally sends and receives network packets at a regular rate. If the network begins to be saturated, Sybase ASE can experience delays in network I/O. The Network Delays statistic reflects the number of times network I/O activity was delayed.

**Metrics**
If you see a network contention rate greater than 1%, it could indicate a challenged network structure.

**Correction**
Beyond ensuring that the existing network is sufficient for handling the current load (database and non-database), other items to look at from a Sybase-specific standpoint include validating that only the necessary amount of data is being sent and returned to requesting users. You can also examine the default packet size and see if it is too small for the average packet size being sent/received by the Sybase ASE server.

Network Errors

The Network Errors statistic reflects the number of times that network errors were detected by Sybase ASE while reading and writing packets.

**Metrics**
If you consistently see a value much above zero, it could indicate the network structure is challenged.

**Correction**
Beyond ensuring that the existing network is sufficient for handling the current load (database and non-database), other items to look at from a Sybase-specific standpoint include validating that only the necessary amount of data is being sent and returned to requesting users. You can also examine the default packet size and see if it is too small for the average packet size being sent/received by the Sybase ASE server.

Transaction Log Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE I/O page to succinctly communicate the general overall performance levels of I/O:

- Log Writes
- Log Allocations
- ULC Flushes
Log Writes

Transaction Log Writes refers to the number of times Sybase ASE wrote a transaction log page to disk since the last refresh. When the current log page becomes full, Sybase ASE writes it out to disk. Sybase ASE also writes transaction log pages to disk after a transaction commits.

Location Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Transaction Log Analysis Pane

Log Allocations

Transaction Log Allocations refers to the number of times since the last refresh that additional pages were allocated to the transaction log. This statistic gives you a feel for the rate of transaction log growth.

Location Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Transaction Log Analysis Pane

ULC Flushes

ULC Flushes is the total number of times that ULCs (user log caches) were flushed to a transaction log during the sample interval.

Location Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Transaction Log Analysis Pane

Average Number of Writes per Log Page

The Average Number of Writes is the average number of times each log page was written to disk.

Location Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Home > Transaction Log Analysis Pane

Metrics In high throughput applications, this number should be as low as possible. If the transaction log uses 2K I/O, the lowest possible value is 1; with 4K log I/O, the lowest possible value is .5, since one log I/O can write 2 log pages. In low throughput applications, the number will be significantly higher. In very low throughput environments, it may be as high as one write per completed transaction.

Workload Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE I/O page to succinctly communicate the general overall performance levels of I/O:

- Top I/O Hogs
Top I/O Hogs

The Top I/O Process statistic identifies the processes that has currently caused the most I/O usage on the database. The table below describes the information available from the Top I/O Hogs view of the I/O page:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPID</td>
<td>The process ID.</td>
</tr>
<tr>
<td>Login</td>
<td>The login name the session is using.</td>
</tr>
<tr>
<td>Physical I/O</td>
<td>The physical amount of I/O the process is using.</td>
</tr>
<tr>
<td>% Used</td>
<td>Percent of total I/O on the server this process is consuming.</td>
</tr>
</tbody>
</table>

Correction: If any one session uses more than 50% of a total resource (CPU, memory, etc.) you should drill down into that particular session and investigate the cause.

Databases tab

The database I/O statistic displays the major I/O statistics as they relate to each associated database. The table below describes the information available from the I/O Databases detail tab:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Logical Reads</td>
<td>The number of logical reads associated with the database.</td>
</tr>
<tr>
<td>Physical Reads</td>
<td>The number of physical reads associated with the database.</td>
</tr>
<tr>
<td>APF Reads</td>
<td>The number of asynchronous pre-fetch buffer reads associated with the database.</td>
</tr>
<tr>
<td>Pages Read</td>
<td>The number of pages read associated with the database.</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>The number of physical writes associated with the database.</td>
</tr>
<tr>
<td>Pages Written</td>
<td>The number of pages written to the associated database.</td>
</tr>
<tr>
<td>Rows Inserted</td>
<td>The number of rows inserted in the associated database.</td>
</tr>
<tr>

</tbody>
</table>

**Correction**

The major guidelines for improving I/O performance in Adaptive Server are as follows:

- Spread data across disks to avoid I/O contention.
- Isolate server-wide I/O from database I/O.
- Separate data storage and log storage for frequently updated databases.
- Keep random disk I/O away from sequential disk I/O.
- Mirror devices on separate physical disks.
- Partition tables to match the number of physical devices in a segment.

**Objects tab**

The following views are used on the Performance Analyst for Sybase ASE I/O Drilldown Objects to succinctly communicate the general overall performance levels of I/O:

- Index Scans
- Open Object I/O
Index Scans

The following views are used on the Index Scans view of I/O Drilldown Objects to succinctly communicate the general overall performance levels of I/O:

- **Ascending Scans**
- **DOL Ascending Scans**
- **DOL Descending Scans**
- **Descending Scans**

**Ascending Scans**

The Ascending Scans value represents the number of forward scans on allpages-locked tables.

**Location**  
Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Objects tab

**DOL Ascending Scans**

The DOL value represents the number of forward scans on data-only-locked tables.

**Location**  
Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Objects tab

**DOL Descending Scans**

The DOL Descending Scans value represents the number of backward scans on allpages-locked tables.

**Location**  
Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Objects tab

**Descending Scans**

The Descending Scans value represents the number of backward scans on data-only-locked tables.

**Location**  
Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Objects tab

**Open Object I/O**

The Open Object I/O view displays a grid that shows a list of each object on the selected database that is either open, or has been open, and related I/O activity.

The table below describes the information available on the Open Object I/O grid:
I/O (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>

</tbody>
</table>

Location: [Sybase ASE Performance Analyst Statistics](#I/O (DBArtisan - Sybase ASE Performance Analyst)) > Objects tab

Metrics: Objects are only removed from the list if the configured number of “open objects” is exceeded. Then they are aged out to make room for newly opened objects.

**Network tab**

The Network tab of the I/O Detail view presents the following statistics:

- Network I/O Summary
- Network I/O by Engine
- Network I/O by Session
Network I/O Summary

Here you see a summary of data that includes the following statistics:

Packets Sent: Total Packets Sent reflects the number of times Sybase ASE sent a packet to a client application.

Packets Received: Total Packets Received reflects the number of times Sybase ASE received a packet from a client application.

Bytes Sent: Total Bytes Sent reflects the number of bytes sent to Sybase ASE since the last refresh.

Bytes Received: Total Bytes Received reflects the number of bytes received by Sybase ASE since the last refresh.

Network I/O by Engine

The statistics, presented in tabular format, include:

- **Engine**: The name of the engine under scrutiny.
- **Packets Sent**: The number of packets sent by the engine.
- **Packets Received**: The number of packets received by the engine.
- **Bytes Sent**: The number of bytes sent by the engine.
- **Bytes Received**: The number of bytes received by the engine.

Network I/O by Session

This view shows the amount of network I/O committed by registered sessions on the Sybase ASE Server.

Presented in tabular format, you see:

- **Login**: The log in name used by the session.
- **SPID**: The process ID.
- **KPID**: The kernel process ID.
- **Packets Sent**: The number of packets sent by the session.
- **Packets Received**: The number of packets received by the session.
- **Bytes Sent**: The number of bytes sent by the session.
I/O (Sybase ASE Performance Analyst)

- **Bytes Received**: The number of bytes received by the session.
- **Network Packet Size**: Network packet size used by the current session.

**Location**  
[Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Network tab]

**Metrics**  
This metric can be used to see if a user or batch job is generating more (or less) network traffic than expected. The process’ network traffic, measured in conjunction with overall server network traffic, could help distinguish between process level or network-wide loads being the source of contention.

**Devices tab**

The following statistics are used on the Performance Analyst for Sybase ASE I/O Drilldown Devices to succinctly communicate the general overall performance levels of I/O:

- **Device I/O Summary**
- **Device I/O Type**
- **Real Time Device I/O**

**Device I/O Summary**

Devices are accessed repeatedly in a dynamic Sybase ASE environment to satisfy user requests for data, to handle write activity that records transactions in a database’s transaction log, and to manage other I/O operations. Viewing the I/O activity for each device is a good way to see what the “hot” devices are in a Sybase ASE server with respect to I/O usage. The same information can be used to spot heavy database usage in systems where the device-to-database mappings are one-to-one.

The table below describes the information available in the Device I/O Summary view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device</td>
<td>The device’s name.</td>
</tr>
<tr>
<td>APF Reads</td>
<td>The number of asynchronous pre-fetch buffer reads associated with the database.</td>
</tr>
<tr>
<td>Physical Reads</td>
<td>The number of physical reads associated with the database.</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>The number of physical writes associated with the database.</td>
</tr>
<tr>
<td>Total I/O</td>
<td>The combined total of read and write operations.</td>
</tr>
</tbody>
</table>
I/O (Sybase ASE Performance Analyst)

Location  Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Devices tab

Metrics  If devices have one-to-one relationships with user databases, you can quickly tell which databases are experiencing the most demand on a server. If the device-to-physical drive/file system is a one-to-one relationship, you can also spot which physical drives on a server are getting the heaviest workouts. For servers that have many drives, it is normally desirable to spread devices across different physical drives and controllers so contention does not occur at the disk level. In addition, separating databases and their corresponding logs is normally recommended so that each is located on a distinct physical drive. If possible, write-intensive devices, like log devices, are best suited for non-RAID5 scenarios.

Correction If device hit rates are low, you can add more devices or redistribute objects among different devices. Typically, segments can be used to redistribute objects among different devices or physical hard disks. Common techniques include placing tables and indexes on different segments and partitioning large tables.

Device I/O Type

The Device I/O Type view shows the type of I/O registering against each configured device.

Devices are accessed repeatedly in a dynamic Sybase ASE environment to satisfy user requests for data, to handle write activity that records transactions in a database’s transaction log, and to manage other I/O operations. Viewing the I/O activity for each device is a good way to see what the "hot" devices are in a Sybase ASE server with respect to I/O usage. The same information can be used to spot heavy database usage in systems where the device-to-database mappings are one-to-one.

The table below describes the information available from the Device I/O Type detail view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device</td>
<td>The name of the device.</td>
</tr>
<tr>
<td>I/O Type</td>
<td>The type of I/O.</td>
</tr>
<tr>
<td>I/O Time (sec)</td>
<td>The amount of time, in seconds, spent performing I/O operations.</td>
</tr>
<tr>
<td>Total I/O</td>
<td>The combined total of read and write operations.</td>
</tr>
</tbody>
</table>
Location  Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Devices tab

Metrics  If devices have one-to-one relationships with user databases, you can quickly tell which databases are experiencing the most demand on a server. If the device-to-physical drive/file system is a one-to-one relationship, you can also spot which physical drives on a server are getting the heaviest workouts. For servers that have many drives, it is normally desirable to spread devices across different physical drives and controllers so contention does not occur at the disk level. In addition, separating databases and their corresponding logs is normally recommended so that each is located on a distinct physical drive. If possible, write-intensive devices, like log devices, are best suited for non-RAID5 scenarios.

Correction  If device hit rates are low, you can add more devices or redistribute objects among different devices. Typically, segments can be used to redistribute objects among different devices or physical hard disks. Common techniques include placing tables and indexes on different segments and partitioning large tables. If device loads appear skewed (one device has much more activity than others), you should focus attention on that device. Again, redistributing objects can lessen the device's workload.

Real Time Device I/O

Devices are accessed repeatedly in a dynamic Sybase ASE environment to satisfy user requests for data, to handle write activity that records transactions in a database’s transaction log, and to manage other I/O operations. Viewing the current, real-time I/O activity for each device is a good way to see what the “hot” devices are in a Sybase ASE server with respect to I/O usage. The same information can be used to spot heavy database usage in systems where the device-to-database mappings are one-to-one.

The table below describes the information available on the Real Time Device I/O detail view:
I/O (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device</td>
<td>The logical name of the device.</td>
</tr>
<tr>
<td>Physical Name</td>
<td>The physical name of the device.</td>
</tr>
<tr>
<td>APF Reads</td>
<td>The number of asynchronous pre-fetch buffer reads associated with the database.</td>
</tr>
<tr>
<td>Physical Reads</td>
<td>Number of buffers read from disk.</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>Number of buffers written to disk.</td>
</tr>
<tr>
<td>I/O Time (Secs)</td>
<td>The amount of time, in seconds, spent performing I/O operations.</td>
</tr>
<tr>
<td>Semaphore Requests</td>
<td>The number of device semaphore requests immediately granted on the device.</td>
</tr>
<tr>
<td>Semaphore Waits</td>
<td>The number of tasks forced to wait for synchronization of an I/O request.</td>
</tr>
</tbody>
</table>

Location  
Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Devices tab

Metrics  
The amount of Reads, APF Reads, and Writes can help you spot overworked devices. You should also keep your eye on the semaphore waits and I/O time for each device to help you determine devices that are experiencing I/O related delays.

Correction  
If device hit rates are low, you can add more devices or redistribute objects among different devices. Typically, segments can be used to redistribute objects among different devices or physical hard disks. Common techniques include placing tables and indexes on different segments and partitioning large tables. If device loads appear skewed (one device has much more activity than others), you should focus attention on that device. Again, redistributing objects can lessen the device's workload.

**Engines Tab**

In symmetric multiprocessing (SMP) environments, a DBA can configure the Sybase ASE server to use more than one "engine," which represents a certain amount of CPU power. By default, Sybase ASE configures one engine for use. If you have a server machine with multiple CPUs, you can enable more engines to take advantage of the machine's additional processing ability.

The Engines tab of the I/O Detail view displays information with respect to how each engine is handling I/O. The table below describes the information available on the Engines tab of the I/O Detail view:
I/O (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Engine</td>
<td>The name of the configured engine.</td>
</tr>
<tr>
<td>Completed I/Os</td>
<td>The number of I/Os completed during the sample interval.</td>
</tr>
<tr>
<td>Outstanding I/Os</td>
<td>The number of I/Os left outstanding during the sample interval.</td>
</tr>
</tbody>
</table>

**Tip:** To configure the grid to show/hide row numbers, use the Options Editor.

**Location** Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Devices tab

**Metrics** If the number of outstanding I/Os remains high or increases during periods of heavy activity, there may not be enough engines configured for the system.

**Correction** If the server machine has multiple CPUs, you can configure more engines for Sybase ASE to use by following this process: Use the `sp_configure` procedure to change the current engine configuration. For example, to change the number of engines from one to two, you would run: `sp_configure * max online engines *,2'. Stop and restart the Sybase ASE server.

### Index Scans Tab

Indexes are accessed frequently in dynamic Sybase ASE server environments. The type of index access often determines the response time an end user experiences. Single row index accesses are the quickest, and complete index scans are the most time consuming (for large indexes at least).

The Index Scans tab of the I/O Detail view presents information with respect to index scans. The table below describes the information available on the Index Scans tab of the I/O Detail view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan Type</td>
<td>The type of index scan.</td>
</tr>
<tr>
<td>Count</td>
<td>The number of scans per type for the sample interval.</td>
</tr>
</tbody>
</table>

**Location** Sybase ASE Performance Analyst Statistics > I/O (DBArtisan - Sybase ASE Performance Analyst) > Devices tab

**Metrics** There are two basic scan types - ascending and descending. For ascending scans, Sybase ASE moves up the index page chain from beginning to end. Sybase ASE follows the page chain in reverse order for descending scans. Descending scans are normally the result of requests made for data by descending column order. Within ascending and descending scans, a data-only lock, or DOL, styled access can also occur.
Space (Sybase ASE Performance Analyst)

In addition to a Home page, the Space category of Sybase ASE Performance Analyst includes the following tabbed pages:

- Databases tab
- Devices tab

Home

The Space performance category view displays the following vital Sybase ASE space statistics:

- Space Analysis Pane
- Transaction Log Analysis
- Bottleneck Analysis Pane
- Device Analysis Pane

Space Analysis Pane

A Sybase ASE Server is broken up into many different databases, each of which has its own level of activity. The Space Analysis section displays a summary of activities that have occurred within each database. It also displays the total number of databases defined on the Sybase ASE server.

The table below describes the database information available on the Space Analysis view:
Space (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>The name of the Sybase ASE database.</td>
</tr>
<tr>
<td>Total Space (MB)</td>
<td>The total amount of space allocated to the database expressed in MB.</td>
</tr>
<tr>
<td>Free Space (MB)</td>
<td>The amount of space currently free expressed in MB.</td>
</tr>
<tr>
<td>Used Space (MB)</td>
<td>The amount of space currently in use, expressed in MB.</td>
</tr>
<tr>
<td>Percent Free</td>
<td>The available free space on the database, expressed as a percentage.</td>
</tr>
<tr>
<td>Log Total Space (MB)</td>
<td></td>
</tr>
<tr>
<td>Log Free Space (MB)</td>
<td></td>
</tr>
<tr>
<td>Log Used Space (MB)</td>
<td></td>
</tr>
<tr>
<td>Log Percent Free</td>
<td></td>
</tr>
<tr>
<td>Log Percent Used</td>
<td></td>
</tr>
</tbody>
</table>

Transaction Log Analysis

The following statistics are used on the Performance Analyst for Sybase ASE Space page to succinctly communicate the general overall performance levels of space related metrics:

- Transaction Log Analysis

Transaction Log Analysis

The Transaction Log Analysis view indicates if any transaction log for a database in the Sybase ASE server is approaching low levels of available free space. The table below describes the information available on the Transaction Log Analysis grid:

<table>
<thead>
<tr>
<th>Axis</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Percent Space Used</td>
<td>The amount of space currently used in the log, expressed as a percentage.</td>
</tr>
<tr>
<td>Databases</td>
<td>The name of the Sybase ASE database.</td>
</tr>
</tbody>
</table>
Metrics

If the transaction log runs out of space, no transactions can take place in the database until you free space in the log.

Correction

If a database log consistently approaches its limit on used space, there are a few actions a DBA can take to prevent a database from freezing. A backup (dump) of the log can be taken: 

- If log backups are not required for disaster recovery, the truncate log on checkpoint option can be set for the database. Setting this option deletes any space devoted to transactions in the log that have already completed when a database checkpoint occurs. You can extend the log onto a new device. Or, if space exists on the device on which the database log currently resides, you can allocate more space for the log on the current device.

Bottleneck Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE Space page to succinctly communicate the general overall performance levels of space related metrics:

- Devices low on space

The following statistics, available on this pane, are duplicates of statistics available on the Bottleneck Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- Databases Low on Space
- Logs Low on Space

Devices low on space

This metric indicates if any device in the Sybase ASE server is approaching low levels of available free space.
The environment of the particular Sybase ASE server, as well as your work style dictate the metrics you should use to evaluating a device that is running into trouble with space. Many DBAs create devices that parallel a single, corresponding database in size, and therefore, such devices show 100% utilization. Other DBAs create large devices that are not completely utilized.

If a device has become too full, a DBA can begin the process of manually relocating databases from it onto other devices. The process of moving logs is easier and can be accomplished via singular commands (sp_logdevice).

### Device Analysis Pane

The Device Analysis view presents space related details about a selected device located on the Sybase ASE server. The table below describes the information available on the Device Analysis view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Devices</td>
<td>Total number of devices configured on the server.</td>
</tr>
<tr>
<td>Device Name</td>
<td>The name of the device.</td>
</tr>
<tr>
<td>Physical Name</td>
<td>The name used by the operating system to identify the device.</td>
</tr>
<tr>
<td>Total Space (MB)</td>
<td>Total space allocated on this device in MB.</td>
</tr>
<tr>
<td>Used Space (MB)</td>
<td>Total space, in MB, currently in use on the device.</td>
</tr>
<tr>
<td>Free Space (MB)</td>
<td>Amount of space that has not been allocated on this device.</td>
</tr>
<tr>
<td>Percent Free (MB)</td>
<td>The available free space on the database, expressed as a percentage.</td>
</tr>
<tr>
<td>Percent Used (MB)</td>
<td>The amount of space used on the database, expressed as a percentage.</td>
</tr>
</tbody>
</table>
Location  Sybase ASE Performance Analyst Statistics > Space (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  The environment of the particular Sybase ASE server as well as your work style dictate the metrics you should use to evaluate a device that is running into trouble with space. Many DBAs create devices that parallel a single, corresponding database in size, and therefore, such devices show 100% utilization. Other DBAs create large devices that are not completely utilized.

Correction  If a device has become too full, a DBA can begin the process of manually relocating databases from it onto other devices. The process of moving logs is easier and can be accomplished via singular commands (sp_logdevice).

Databases tab

The following views are used on the Performance Analyst for Sybase ASE Space drill-down page to succinctly communicate the general overall performance levels of space related metrics:

  - Database Object Summary
  - Database Object Detail

Database Object Summary

A Sybase ASE server contains many databases, some of which are devoted to system-level activities (the master and tempdb databases, for example) and others that hold user data. The database overview displays details about the space situation for each database in a Sybase ASE server, including the total, used, and free space. The percentage used amount for each database is also shown.

The table below describes the information available on the Database Object Summary detail view:
## Space (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>

<td>Percent Log Free (KB)</td>
<td>The amount of free log space expressed as a percent.</td>
</tr>
</tbody>
</table>
Space (Sybase ASE Performance Analyst)

Location Sybase ASE Performance Analyst Statistics > Space (DBArtisan - Sybase ASE Performance Analyst) > Databases tab

Metrics If a database’s used space percent amount goes above 90%, and the database is dynamic in nature (meaning that users are constantly adding and modifying data), then you should take action to ensure that the database does not run out of available free space.

Correction If the percent used amount of a database is approaching problematic levels, there are two ways you can rectify the situation:

- **If the database device that the database currently resides on contains additional free space, you can ALTER the database to consume more available space on that device.**
- **If the database device that the database currently resides on does not contain additional free space, you can do one of the following:**
  - Create a new device and issue an ALTER for the database to use that device for space in addition to those currently used.
  - Choose another existing device that has free space and ALTER the database to use that device in addition to those currently in use.

Database Object Detail

Tables and indexes comprise every Sybase ASE database. The Database Object Detail view presents space-related information about tables and indexes. You can choose to view object details by table or index. Or, view objects matching a pattern you specify in the text box.

The table below describes the information available in the Database Object Detail view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>The owner of the table or index.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table.</td>

<td>Extent Estimate</td>
<td>An estimation as to the number of extents for the object.</td>
</tr>
</tbody>
</table>
Devices tab

The following statistics are used on the Performance Analyst for Sybase ASE Space Drill-down Devices to succinctly communicate the general overall performance levels of space related metrics:

- Device Summary
- Device Fragment Detail

Device Summary

The Device Summary view presents space related details about a selected device located on the Sybase ASE server. The table below describes the information available in the Device Summary detail view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device Name</td>
<td>The logical name of the device.</td>
</tr>
<tr>
<td>Physical Name</td>
<td>The physical name of the device.</td>
</tr>
<tr>
<td>Total Space (MB)</td>
<td>Amount of space configured when the device was created.</td>
</tr>
<tr>
<td>Used Space (MB)</td>
<td>Amount of space available to any database (via the create or alter database commands).</td>
</tr>
<tr>
<td>Free Space (MB)</td>
<td>The amount of free space left in the device.</td>
</tr>
<tr>
<td>Percent Free</td>
<td>The amount of free space for the device expressed as a percentage of total space.</td>
</tr>
<tr>
<td>Percent Used</td>
<td>The amount of used space for the device expressed as a percentage of total space.</td>
</tr>
</tbody>
</table>
Metrics  If a device’s used space percent amount goes above 90%, you should take action to ensure that the device does not run out of available free space.

Correction If the percent used amount of a device is approaching problem levels, there are two ways you can rectify the situation: Create a new device and issue an ALTER for the database(s) to use that device for space in addition to those currently used. Choose another existing device that has free space and ALTER the database(s) to use that device in addition to those currently in use.

Device Fragment Detail

Space from a device is allocated among one or more databases on a Sybase ASE server. The Device Fragment Detail section presents all databases and their space fragments that reside on a particular device.

The table below describes the information available on the Device Fragment Detail view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of database fragment (data only, log only, data and log).</td>
</tr>
<tr>
<td>Size (MB)</td>
<td>The size of the fragment in MB.</td>
</tr>
</tbody>
</table>

Databases (Sybase ASE Performance Analyst)

In addition to a Home page, the Databases category of Sybase ASE Performance Analyst includes the following tabbed pages:

- Overview Tab
- Objects Tab
- Configuration Tab
- Engines Tab

Home

The Database performance category view displays the following vital Sybase ASE database statistics:

- Server Analysis Pane
- Bottleneck Analysis Pane
- Backup Analysis Pane
- Engine Analysis Pane
- Workload Analysis Pane

Server Analysis Pane

The following statistic is used on the Performance Analyst for Sybase ASE Databases Page to succinctly communicate the general overall performance levels of database specific metrics:

- Sample Query Response Time

The following statistics, available on this pane, are duplicates of statistics available on the Key Ratio Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- CPU Busy
- I/O Busy

Sample Query Response Time

Performance Analyst allows you to define a query that is periodically run and timed by the product. The sample query helps you gauge the response time effectiveness of the Sybase ASE server.
Bottleneck Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE Databases page to succinctly communicate the general overall performance levels of database specific metrics:

- **Databases with Suspect Pages**
- **Engine Configuration Limit**
- **Index Maintenance from Deletes**
- **Index Maintenance from Insert/Updates**
- **Operating System Limit**
- **Page Splits**
- **Server Configuration Limit**

The following statistics, available on this pane, are duplicates of statistics available on the Bottleneck Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- **Suspect Databases**

Databases with Suspect Pages

Suspect objects normally indicate an internal problem in a server. They can also indicate that physical damage has occurred to part of a database.
Databases (Sybase ASE Performance Analyst)

Location Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics Suspect objects have no place in a production database. If you identify any suspect objects, you should take immediate action.

Correction If the suspect object is an index, you could try dropping and recreating it, or use the DBCC REINDEX command. Other damaged objects can complete rebuilding the database. A suspect database can be a difficult thing to recover from quickly. There are times when the cache of the database is suspect and not the database itself. Stopping and starting the Sybase ASE server can verify if this is the case. If the database itself is actually damaged, there could be a true recovery situation. The suspect database can be dropped using the DBCC DBREPAIR DROPDB command. You would then need to recreate the database and perform a recovery operation using the most recent database dump.

Engine Configuration Limit

An engine can exceed its limit for outstanding asynchronous disk I/O requests based on the maximum number of asynchronous I/Os per engine parameter.

Location Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics You can change this limit with the maximum asynchronous I/Os per engine configuration parameter.

Index Maintenance from Deletes

Indexes can considerably speed data access operations. The trade-off, however, is that indexes require maintenance whenever indexed columns are added to, modified, or removed in the parent table. The index maintenance from insert/updates metric provides a count of how many index maintenance operations have occurred from insert or update operations.
Databases (Sybase ASE Performance Analyst)

Location  Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Some index maintenance activity is to be expected (unless you are operating in a read-only environment), but excessive index maintenance can quickly become a bottleneck in heavy OLTP environments.

Correction  If you observe a lot of index maintenance activity, you should begin a periodic review of your indexing schemes to ensure that all indexes currently maintained on the system are used and necessary. If you are using Sybase ASE 12.5.03 or later (and have installed the monitoring tables), you can use Performance Analysts object I/O drill-down view to diagnose which tables and indexes are the targets of heavy maintenance activity.

Index Maintenance from Insert/Updates

Indexes can considerably speed data access operations. The trade-off, however, is that indexes require maintenance whenever indexed columns are added to, modified, or removed in the parent table. The index maintenance from insert/uploads metric provides a count of how many index maintenance operations have occurred from insert or update operations.

Location  Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Some index maintenance activity is to be expected (unless you are operating in a read-only environment), however excessive index maintenance can quickly become a bottleneck in heavy OLTP environments.

Correction  If you observe a lot of index maintenance activity, you should begin a periodic review of your indexing schemes to ensure that all indexes currently maintained on the system are used and necessary. If you are using Sybase ASE 12.5.03 or higher (and have installed the monitoring tables), you can use Performance Analysts object I/O drill down view to diagnose which tables and indexes are the targets of heavy maintenance activity.

Operating System Limit

When a Sybase ASE server begins to experience I/O delays, the result can be a very dissatisfied user community. When such problems occur, you should investigate the Sybase ASE or operating system limits. It could be that I/O operations are being blocked by one or both.

The Operating System Limit statistic shows nonzero numbers if Sybase ASE detects that the limit for asynchronous I/Os has been exceeded.
Page Splits

When data is inserted or updated in a table, Sybase ASE may reorganize the data storage in the table’s index pages. When an index page becomes full, but a DML operation demands room on that page, Sybase ASE moves half the rows to a new page to accommodate the request. This reorganization is known as a page split.

Server Configuration Limit

When a Sybase ASE server begins to experience I/O delays, the result can be a very dissatisfied user community. When such problems begin to occur, you should investigate the Sybase ASE or operating system limits. It could be that I/O operations are being blocked by one or both limits.

The Server Configuration Limit statistic shows nonzero numbers if Sybase ASE has exceeded its limit for the number of asynchronous disk I/O requests that can be outstanding for the server at one time.

Backup Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE Databases page to succinctly communicate the general overall performance levels of database specific metrics:

- Backup Server Status
- Last Transaction Log Dump
Backup Server Status

The Backup Server Status value indicates whether or not the Backup Server is up and running.

Location: Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Home > Backup Analysis Pane

Last Transaction Log Dump

The Last Transaction Log Dump value represents the last time the transaction was dumped for the associated database.

Location: Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Home > Backup Analysis Pane

Engine Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE Databases page to succinctly communicate the general overall performance levels of database-specific metrics:

- Engine Busy %
- Maximum Engines

Engine Busy %

The Engine Busy % value represents the percentage of time the Adaptive Server Kernel is busy executing tasks on each Adaptive Server engine (rather than time spent idle).
Metrics

When Adaptive Server has no tasks to process, it enters a loop that regularly checks for network and completed disk I/Os, and tasks in the run queue. Operating system commands to check CPU activity may show high usage for an Adaptive Server engine because they are measuring the looping activity, while Engine Busy % does not include time spent looping it is considered idle time.

Correction

This category can help you decide whether there are too many or too few Adaptive Server engines. Adaptive Server’s high scalability is due to tunable mechanisms that avoid resource contention. If values are consistently very high (more than 90%), it is likely that response time and throughput could benefit from an additional engine.

Maximum Engines

The Maximum Engines value represents the maximum number of engines currently connected.

Workload Analysis Pane

The following statistic is used on the Performance Analyst for Sybase ASE Databases page to succinctly communicate the general overall performance levels of database specific metrics:

- Workload Analysis

Workload Analysis

The Sybase ASE Server is broken up into many different databases, each of which has its own levels of activity. The Workload Analysis section displays a summary of resource consumption across all databases.

The table below describes the information available in the Workload Analysis section:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Name</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Connections</td>
<td>The number of connections to the database.</td>
</tr>
<tr>
<td>Blocked Users</td>
<td>The number of users currently blocked on the associated database.</td>
</tr>
<tr>
<td>Total Memory</td>
<td>The total amount of memory currently being used by the database.</td>
</tr>
<tr>
<td>Total I/O</td>
<td>The total amount of I/O currently being registered by the database.</td>
</tr>
<tr>
<td>Total CPU</td>
<td>The total amount of cumulative CPU for all processes connected to the database.</td>
</tr>
</tbody>
</table>

Location [Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Home > Engine Analysis Pane](#)

### Overview Tab

The following statistics are used on the Performance Analyst for Sybase ASE Databases Detail Overview Page to succinctly communicate the general overall performance levels of database specific metrics:

- Database Size Analysis
- Database Object Analysis
- Database User Analysis
- Database Summary

### Database Size Analysis

The Database Size Analysis chart displays each database in terms of its total percentage of size to the total size of all databases on the Sybase ASE Server.

Location [Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Overview Tab](#)

### Database Object Analysis

The Database Object Analysis chart displays each database in terms of its terms of its total percentage of objects to the total objects for all databases on the Sybase ASE Server.
Database User Analysis

The Database User Analysis chart displays each database in terms of its total percentage of user accounts to the total user accounts of all databases on the Sybase ASE Server.

Location  
Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Overview Tab

Database Summary

This section displays summarized metadata for all defined databases on the Sybase ASE Server.

Note: Right-click any column heading to sort the column(s) in ascending or descending order.

The information available in the Database Summary table is described below:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Created</td>
<td>Gives the month/day/year and hour/minutes/second on which the database was first generated.</td>
</tr>
<tr>
<td>Owner</td>
<td>Lets you see who owns the database.</td>
</tr>
<tr>
<td>Database Size (MB)</td>
<td>Displays the size of the database in megabytes.</td>
</tr>
<tr>
<td>Log Size (MB)</td>
<td>Displays the log size in megabytes.</td>
</tr>
<tr>
<td>Tables</td>
<td>Gives the number of tables in the database.</td>
</tr>
<tr>
<td>Indexes</td>
<td>Displays the number of indexes in the table.</td>
</tr>
<tr>
<td>Users</td>
<td>Lets you see the number of database users.</td>
</tr>
<tr>
<td>Last Trans Log Backup</td>
<td>Let you see the last month/day/year and hour/minutes/second on which the transaction logs were most recently backed-up.</td>
</tr>
<tr>
<td>Suspect</td>
<td>Lets you see in YES or NO format whether the database is suspect.</td>
</tr>
<tr>
<td>Suspect Pages</td>
<td>Lets you see in YES or NO format whether there are any suspect pages in the database.</td>
</tr>
</tbody>
</table>
Location  Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst)  
> Overview Tab

Metrics The following items merit attention: Any critical database that shows a last transaction log backup date that is older than the database’s required backup needs. Any database that shows a status of offline or suspect.

Objects Tab

The following statistics are used on the Performance Analyst for Sybase ASE Databases Detail Objects Page to succinctly communicate the general overall performance levels of database specific metrics:

- Database Object Detail
- Suspect Objects
- Cache Bindings

Database Object Detail

This view gives you detailed information for each database. Select the database you want to scrutinize and choose between reviewing tables or indexes. You can also enter a preference to see objects matching a pattern you specify in the text box. The table below describes the information available in the Database Object Detail table:
Databases (Sybase ASE Performance Analyst)

### Column Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>Displays the name of the table or index owner, depending on the view you selected.</td>
</tr>
<tr>
<td>Table/Index Name</td>
<td>Displays the name of the table or index, depending on the view you selected.</td>
</tr>
<tr>
<td>Segment Name</td>
<td>Lets you see associated table/index segment.</td>
</tr>
<tr>
<td>Locking Scheme</td>
<td>TABLE ONLY: Lets you see the type of locking scheme the table uses.</td>
</tr>
<tr>
<td>Last Statistic Date</td>
<td>TABLE ONLY: Lets you see the most recent date and time table statistics were gathered.</td>
</tr>
<tr>
<td>Row Count</td>
<td>TABLE ONLY: Lets you see the number of rows in the target table.</td>
</tr>
<tr>
<td>Reserved (KB)</td>
<td>Lets you see the amount of space reserved for the target object in kilobytes.</td>
</tr>
<tr>
<td>Avg Row Size</td>
<td>TABLE ONLY: Lets you see the average row size for the target table.</td>
</tr>
<tr>
<td>Tree Depth</td>
<td>INDEX ONLY: Lets you see the number of layers, or depth, of the index.</td>
</tr>
<tr>
<td>Leaf Count</td>
<td>INDEX ONLY: Lets you see the number of leaf-level pages in the index.</td>
</tr>
<tr>
<td>Leaf Row Size</td>
<td>INDEX ONLY: Lets you see the row size for each index leaf.</td>
</tr>
</tbody>
</table>

Location: [Sybase ASE Performance Analyst Statistics](#) > [Space (Sybase ASE Performance Analyst)](#) > [Objects Tab](#)

### Suspect Objects

Suspect objects normally indicate an internal problem in a server or that physical damage has occurred to part of a database. The table below describes the information available in the Suspect Objects grid:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>Displays the name of the table owner.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The affected table’s name.</td>
</tr>
<tr>
<td>Index Name</td>
<td>The affected index’s name.</td>
</tr>
</tbody>
</table>
Location  Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Objects Tab

Metrics Suspect objects have no place in a production database. If any suspect objects are identified, you should immediately take action.

Correction If the suspect object is an index, you could try dropping and re-creating it, or use the DBCC REINDEX command. Other damaged objects can complete rebuilding the database. A suspect database can be a difficult thing to recover from quickly. There are times when the cache of the database is suspect and not the database itself. Stopping and starting the Sybase ASE server can verify if this is the case. If the database itself is actually damaged, there could be a true recovery situation. The suspect database can be dropped using the DBCC DBREPAIR DROPDB command. You would then need to re-create the database and perform a recovery operation using the most recent database dump.

## Cache Bindings

The Sybase ASE cache areas are devoted to facilitating the transfer of data and information between clients and the Sybase ASE database. Tables and/or indexes can be assigned to various caches in hopes of speeding up access to table or index information. The Cache Bindings Detail section provides information about the current cache bindings of tables and/or indexes. The table below describes the information available in the Cache Bindings chart:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>The object owner’s name.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The table’s name.</td>
</tr>
<tr>
<td>Index Name</td>
<td>The index’s name.</td>
</tr>
<tr>
<td>Cache Binding</td>
<td>The name of the cache associated with the table or index.</td>
</tr>
</tbody>
</table>

Location  Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Objects Tab

Metrics The objects best suited for being bound to a cache include frequently accessed objects that are oftentimes small in nature. Large tables that are scanned are normally not suitable for being bound to a cache and are best left to being indexed properly.

## Configuration Tab

The following statistics are used on the Performance Analyst for Sybase ASE Databases Detail Configuration Page to succinctly communicate the general overall performance levels of database specific metrics:

- **Database Configuration**
Database Configuration

The Database Configuration view allows you to see all the settings currently configured parameters and their settings on the associated database. Select a database from the drop-down list to see the parameter/setting information.

Location Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Configuration Tab

Server Configuration

The Server Configuration view allows you to see all the settings of currently configured parameters on the Sybase ASE Server. Select a database from the drop-down list to see the following information in the Server Configuration grid:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Lets you see the name of the configured parameter.</td>
</tr>
<tr>
<td>Configured Value</td>
<td>Displays the configured value of the parameter.</td>
</tr>
<tr>
<td>Run Value</td>
<td>Displays the run value.</td>
</tr>
<tr>
<td>Minimum</td>
<td>Displays the minimum configuration value.</td>
</tr>
<tr>
<td>Maximum</td>
<td>Displays the maximum configuration value.</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Indicates whether or not the parameter is dynamic or not.</td>
</tr>
</tbody>
</table>

Location Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Configuration Tab

Engines Tab

The following statistic is used on the Performance Analyst for Sybase ASE Databases Detail Engines Page to succinctly communicate the general overall performance levels of database specific metrics:

- Database I/O

Database I/O

The Database I/O view on the Engines tab of the Databases Detail view allows you to see statistics about database objects. The table below describes the information available to you about Database I/O:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the engine.</td>
</tr>
<tr>
<td>Start Date/Time</td>
<td>The date and time when the Sybase ASE engine started.</td>
</tr>
<tr>
<td>Stop Date/Time</td>
<td>The date and time when the Sybase ASE engine stopped.</td>
</tr>
<tr>
<td>OSPID</td>
<td>The operating system process ID.</td>
</tr>
<tr>
<td>KPID</td>
<td>The kernel process ID.</td>
</tr>
<tr>
<td>Status</td>
<td>The engine’s current status and whether it is connected or not.</td>
</tr>
<tr>
<td>Context Switches</td>
<td>The current number of context switches registering on the associated engine.</td>
</tr>
<tr>
<td>Current Connections</td>
<td>The current number of connections registering on the associated engine.</td>
</tr>
<tr>
<td>CPU Time</td>
<td>The current amount of CPU time consumed by the associated engine.</td>
</tr>
<tr>
<td>CPU Time (System)</td>
<td>The current amount of system CPU time.</td>
</tr>
<tr>
<td>CPU Time (User)</td>
<td>The current amount of user CPU time.</td>
</tr>
</tbody>
</table>

Location: [Sybase ASE Performance Analyst Statistics > Space (Sybase ASE Performance Analyst) > Configuration Tab](#)
Users (Sybase ASE Performance Analyst)

In addition to a Home page, the Users category of Sybase ASE Performance Analyst includes the following tabbed pages:

- Top Sessions tab
- Locks tab
- Transactions tab
- System Waits tab
- Session Waits tab

Home

The Users performance category view displays the following vital Sybase ASE user statistics:

- Key User Analysis pane
- Bottleneck Analysis Pane
- Index Scan Analysis Pane
- Transaction Analysis - Users
- Workload Analysis Pane

Key User Analysis pane

The following statistics are used on the Performance Analyst for Sybase ASE User page to succinctly communicate the general overall performance levels of user specific metrics:

- Active User Processes
- Extended Procedure Requests
- Inactive User Processes
- Parallel Queries
- Procedure Requests
- System Processes
Active User Processes

The Active User Processes statistic is the total number of active and open threads reported on the Server. Active Sessions displays the number of processes actively performing work.

Location Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Key User Analysis pane

Extended Procedure Requests

The Extended Procedure Requests value represents the number of times extended procedures were executed in the sample interval.

Location Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Key User Analysis pane

Inactive User Processes

The Inactive Sessions statistic represents the total number of threads logged onto the server that are idle at the current time.

Location Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Key User Analysis pane

Metrics A large number of inactive users could indicate user sessions that have mistakenly been left logged on. Since each user thread consumes a portion of memory on the server, to reduce resource usage, you should sever any sessions not needing a connection.

Correction Drill down into the Session Waits page and check sessions that have many seconds idle or that have been logged on for very long periods of time, as indicated by the logon time column. After verifying that a session is no longer necessary, you can KILL it.

Parallel Queries

The Parallel Queries value represents the total number of queries eligible to be run in parallel.

Location Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Key User Analysis pane

Metrics The optimizer determines the best plan, and decides whether a query should be run serially or in parallel and how many worker processes should be used for parallel queries.
Procedure Requests

The Procedure Requests value represents the number of times stored procedures were executed in the sample interval.

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Key User Analysis pane

System Processes

The System processes value represents the total number of threads logged onto the server that are Sybase ASE internal processes.

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Key User Analysis pane

Bottleneck Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE User Home Page to succinctly communicate the general overall performance levels of user specific metrics:

- Average Hash Chain Length
- Average Lock Contention %
- Current Locks
- Deadlock %
- Lock Promotions
- Lock Timeouts
- Total Priority Changes

The following statistics, available on this pane, are duplicates of statistics available on the Bottleneck Analysis Pane of the Home View (Sybase ASE Performance Analyst) page:

- Deadlocks
- Blocked Connections

Average Hash Chain Length

This value represents the average number of locks per hash bucket during the sample interval.
Correction If the average number of locks per hash chain is more than four, consider increasing the size of the hash table. Large inserts with bulk copy are an exception to this guideline. Lock hash chain lengths may be longer during large bulk copies.

**Average Lock Contention %**

The Average Lock Contention % represents the average number of times there was lock contention as a percentage of the total number of lock requests.

Correction If the lock contention average is high, investigate the locks to see if the application is causing a lock contention or deadlock-related problem.

**Current Locks**

There are varieties of operations in Sybase ASE that require the use of locks. The Current Locks statistic represents the number of total locks currently active in Sybase ASE.

Correction If the number of current locks in a Sybase ASE server approaches the Sybase ASE limit for available locks, you can look into increasing the Number of Locks configuration parameter.

**Deadlock %**

A deadlock occurs when two processes have a lock on a separate page or object and each wants to acquire a lock on the other process' page or object. Each waits for the other to release the necessary lock. Sybase ASE constantly checks for deadlocks and, when found, chooses the transaction that has accumulated the least amount of CPU time and terminates the transaction. The server then rolls back that transaction and issues a notification of the event. The other process gets to move forward.

The deadlock % rate displays the percentage of times deadlocks occurred vs. the percentage of locks requested and immediately granted.
Users (Sybase ASE Performance Analyst)

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Immediately investigate a percentage much above zero to prevent the situation from mushrooming. You can easily drill down and discover the exact process(es) holding locks and deadlocks that are blocking out other user activity.

Correction  Well-designed applications can minimize deadlocks by always acquiring locks in the same order. You should always do updates to multiple tables in the same order. Once Sybase ASE discovers a deadlock, it takes action and remedies the situation. Embarcadero Performance Analyst makes it easier to discover how prevalent deadlock activity is on a system; preventing deadlocks from occurring in the first place is more difficult. Those responsible for writing systems can minimize deadlocks by ensuring that applications acquire locks in the same order. Likewise, you should always do updates and other DML that act on multiple tables in the same order. You can also shrink the amount of time that Sybase ASE waits to check for deadlocks by modifying the deadlock checking period configuration parameter.

Lock Promotions

The Lock Promotions value represents the average number of lock promotion types combined per second and per transaction.

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Lock promotions occur when the following escalations take place: "Sh-Page to Sh-Table" - Shared page to shared table. "Ex-Row to Ex-Table" - Exclusive row to exclusive table. "Sh-R to Sh-Table - Shared row to shared table. "Sh-Next-Key to Sh-Table" - Shared next-key to shared table. "Ex-Page to Ex-Table" - Exclusive page to exclusive table.

Correction  If lock contention is high and lock promotion is frequent, you should consider changing the lock promotion thresholds for the tables involved. You can configure the lock promotion threshold either server-wide or for individual tables.

Lock Timeouts

The Lock Timeouts value represents the total number of locks timing out during the sample period.
Users (Sybase ASE Performance Analyst)

Location Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics You can specify the time that a task waits for a lock: At the server level, with the lock wait period configuration parameterFor a session or in a stored procedure, with the set lock wait commandFor a lock table command

Correction Except for lock table, a task that attempts to acquire a lock and fails to acquire it within the time period returns an error message and the transaction is rolled back. Using lock timeouts can be useful for removing tasks that acquire some locks, and then wait for long periods of time blocking other users. However, since transactions are rolled back, and users may simply resubmit their queries, timing out a transaction means that the work needs to be repeated.

Total Priority Changes

Total Priority Changes represent the total number of priority changes during the sample period.

Location Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics It is normal to see some priority switching due to system-related activity. Such priority switching occurs, for example, when: A task sleeps while waiting on a lock - Adaptive Server temporarily raises the task’s priority. The housekeeper task sleeps - Adaptive Server raises the priority to medium while the housekeeper sleeps, and changes it back to low when it wakes up.A task executes a stored procedure - the task assumes the priority of the stored procedure and resumes its previous priority level after executing the procedure.

Correction If you are using logical process management and there are a high number of priority changes compared to steady state values, it may indicate that an application, or a user task related to that application, is changing priorities frequently. Check priority change data for individual applications. You should verify that applications and logins are behaving expected. If you determine that a high-priority change rate is not due to an application or to related tasks, then it is likely due to system activity.

Index Scan Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE User page to succinctly communicate the general overall performance levels of user specific metrics:

- Ascending
- Descending
- DOL Ascending
- DOL Descending
- Total Index Scans
Ascending

The Ascending value represents the number of forward scans on allpages-locked tables.

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Index Scan Analysis Pane

Descending

The Descending statistic represents the number of backward scans on allpages-locked tables.

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Index Scan Analysis Pane

DOL Ascending

The DOL Ascending value represents the number of forward scans on data-only-locked tables.

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Index Scan Analysis Pane

DOL Descending

The DOL Descending value represents the number of backward scans on data-only-locked tables.

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Index Scan Analysis Pane

Total Index Scans

The Total Index Scans statistic represents the total number of index scans (forward and backward).

Location  Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Index Scan Analysis Pane

Transaction Analysis - Users

The following statistics are used on the Performance Analyst for Sybase ASE User page to succinctly communicate the general overall performance levels of user-specific metrics:

- Active Transactions
- Committed Transactions
Active Transactions

The Active Transaction statistic represents a count of the number on in-process transactions for SQL Server.

Location: Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Index Scan Analysis Pane

Committed Transactions

Committed Transactions gives the number of transactions committed since the last refresh inside Performance Analyst. This includes transactions that meet explicit, implicit, and ANSI definitions for committed transactions. Note that multi-database transactions are counted.

Location: Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Index Scan Analysis Pane

Metrics: Multi-database transactions generally incur more overhead than single database transactions (for example, a transaction that modifies two databases is counted as two transactions). They usually involve more log activity and two-phase commits between the different databases, as well as cause more ULC flushes. You can improve performance by reducing the number of multi-database transactions.

Workload Analysis Pane

The following statistics are used on the Performance Analyst for Sybase ASE User page to succinctly communicate the general overall performance levels of user specific metrics:

- Workload Analysis

Workload Analysis

When your phone starts ringing with complaints of performance slowdowns, some of the first questions you should answer are:

- What users are currently connected to the database?
- What resources are they using?
- What are they currently executing?

The Workload Analysis section of the Performance Analyst page provides insight into the leading resource hogs of a server. The table below describes the information available in the Workload Analysis section of the Users page:
## Users (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity</td>
<td>Statistics are presented for the Top CPU Process, Top I/O Process, or Top Memory Process.</td>
</tr>
<tr>
<td>SPID</td>
<td>The process ID.</td>
</tr>
<tr>
<td>Login</td>
<td>The logon name the session is using.</td>
</tr>
<tr>
<td>% Used</td>
<td>The percentage of CPU, I/O, or Memory consumed by the process.</td>
</tr>
</tbody>
</table>

**Location**
Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Home > Workload Analysis Pane

**Metrics**
If any one session appears to be using more than 50% of a total resource (CPU, memory, etc.), then you should drill down into the session to find out what they are currently executing.

## Top Sessions tab

The following statistics are used on the Performance Analyst for Sybase ASE Users Drill-down Top Sessions to succinctly communicate the general overall performance levels of user specific metrics:

- Top I/O Processes
- Top Memory Processes
- Top CPU Processes
- Top Sessions

## Top I/O Processes

The Top I/O Processes statistic identifies the current Sybase ASE process with the highest % of I/O activity.

**Location**
Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Top Sessions tab

**Correction**
If any one session uses more than 50% of a total resource (CPU, memory, etc.), you should drill down into that particular session and investigate the cause.

## Top Memory Processes

The Top Memory Process statistic identifies the Sybase ASE process that currently is using the highest percentage of memory in the database.
Top CPU Processes

The Top CPU Process statistic identifies the Sybase ASE process that currently has the highest percentage of CPU usage in the database.

Top Sessions

When a system experiences heavy activity, sometimes you will find that all the user connections are contributing somewhat equally to the overall load. More often than not, however, one or two user connections are causing most of the activity. It might be that a large batch load or other typical process is running that is perfectly okay for your system. Or it might be a runaway process or other rogue connection that needs to be tracked down and possibly eliminated.

The table below describes the information available on the Top Sessions detail view:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPID</td>
<td>The process ID.</td>
</tr>
<tr>
<td>User</td>
<td>The name of the session user.</td>
</tr>
<tr>
<td>FID</td>
<td>The process ID of the worker process' parent.</td>
</tr>
<tr>
<td>Status</td>
<td>The current status of the session.</td>
</tr>
<tr>
<td>Database</td>
<td>The database the session is attached to.</td>
</tr>
<tr>
<td>Host</td>
<td>The client machine name the session is using.</td>
</tr>
<tr>
<td>Program</td>
<td>This identifies the program being run by the session.</td>
</tr>
<tr>
<td>Mem Usage</td>
<td>The amount of memory being used by the session.</td>
</tr>
<tr>
<td>CPU Time</td>
<td>The cumulative CPU time for the process.</td>
</tr>
<tr>
<td>Physical Reads</td>
<td>The number of physical reads produced by the session.</td>
</tr>
<tr>
<td>Logical Reads</td>
<td>The number of logical reads produced by the session.</td>
</tr>
<tr>
<td>Physical Writes</td>
<td>The number of physical writes generated by the session.</td>
</tr>
</tbody>
</table>
Locks tab

The following statistics are used on the Performance Analyst for Sybase ASE User Drill-down Locks tab to succinctly communicate the general overall performance levels of user specific metrics:

- Locks
- Locks by Lock Type
- Locks by Database

Locks

To modify database information or structures, a user session must obtain a lock on the object to perform its task. In addition to user locks, Sybase ASE itself issues lock requests to carry out its internal duties. The Locks section gives information about the locks currently on the system and also indicates if any blocking situations are occurring. You can elect to show only blocking locks in the Lock detail view.

The table below describes the information available on the Locks detail view:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPID</td>
<td>The process ID.</td>
</tr>
<tr>
<td>User</td>
<td>The name of the current user</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database where the process is running.</td>
</tr>
<tr>
<td>Lock Type</td>
<td>The type of lock (database, table, row id, etc.).</td>
</tr>
<tr>
<td>Object Name</td>
<td>The name of the object involved in the lock.</td>
</tr>
<tr>
<td>Status</td>
<td>The lock's status (waiting or granted).</td>
</tr>
<tr>
<td>Lock Page</td>
<td>The number of pages, if any, that are experiencing locks.</td>
</tr>
<tr>
<td>Lock Class</td>
<td>Lets you see the lock class.</td>
</tr>
<tr>
<td>Host</td>
<td>The client machine name the session is using.</td>
</tr>
<tr>
<td>Program</td>
<td>The executable the process is using against the server.</td>
</tr>
<tr>
<td>Command</td>
<td>The command currently being issued by the process.</td>
</tr>
<tr>
<td>CPU Time</td>
<td>The amount of time the process took to parse, execute, and fetch the data needed to satisfy the process' execution.</td>
</tr>
<tr>
<td>I/O</td>
<td>The amount of I/O activity for the target process.</td>
</tr>
<tr>
<td>Mem Usage</td>
<td>The amount of memory being used by the target process.</td>
</tr>
<tr>
<td>FID</td>
<td>The process ID of the worker process' parent.</td>
</tr>
<tr>
<td>Transaction</td>
<td>The current transactions generated by processes on the Sybase ASE Server</td>
</tr>
</tbody>
</table>
Metrics
A single blocking user has the potential to stop work for nearly all other processes on a small system, and can cause major headaches even on large systems. Blocks are most often caused by user processes holding exclusive locks and not releasing them via a proper COMMIT frequency. Unless a process times out via an application timeout mechanism, or the process has specified a timeout period, a process waiting for a lock will wait indefinitely.

Correction
Once discovered, a blocking lock situation can normally be quickly remedied - the DBA issues a KILL against the offending process, which eliminates the user’s stranglehold on the objects the user was accessing. Other user processes then nearly always complete in an instant. Discovering the blocked lock situation is made easier by using tools like Performance Analyst, but preventing the blocking lock situation in the first place is where it gets tricky. The DBA can drill down into user detail and view all current blocking locks to see exactly which sessions are holding the currently restrictive locks. The culprit of blocking lock scenarios is usually the application design, or the SQL being used within the application itself. Properly coding an application to reference database objects in an efficient order, and then using the right SQL to get the job done, is art. The key to avoiding lock content is to process user transactions in the quickest and most efficient manner possible - something not always easy to do.

Locks by Database

The Locks by Database view represents the total locks occurring on the Sybase ASE Server stratified by which database they are occurring on.

Transactions tab

The Transactions view displays current transactions generated by processes on the Sybase ASE Server.

The table below describes the information available on the Transactions detail view:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPID</td>
<td>The process ID.</td>
</tr>
<tr>
<td>User</td>
<td>The name of the user generating the session.</td>
</tr>
<tr>
<td>Status</td>
<td>The current status of the session.</td>
</tr>
<tr>
<td>Start Time</td>
<td>The time the session started.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of session.</td>
</tr>
<tr>
<td>State</td>
<td>The current state of the session, for example, whether or not it is active.</td>
</tr>
<tr>
<td>Command</td>
<td>The command currently being issued by the session.</td>
</tr>
<tr>
<td>Connection</td>
<td>The amount of memory allocated to the session’s connections</td>
</tr>
<tr>
<td>CPU Time</td>
<td>The amount of time the process took to parse, execute, and fetch the data needed to satisfy the process’ execution.</td>
</tr>
<tr>
<td>Mem Usage</td>
<td>The amount of memory being used by the session.</td>
</tr>
<tr>
<td>Physical I/O</td>
<td>The amount of physical I/O for the session.</td>
</tr>
</tbody>
</table>

**Location**

Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Transactions tab

**Metrics**

Transaction activity is a good measurement of general performance by a user. If the total or committed numbers do not increase over a period of time, either the process is inactive or it may be hung or blocked.

**Correction**

Look at CPU and I/O statistics to see if any activity for the process is being noted there.

### System Waits tab

The following statistics are used on the Performance Analyst for Sybase ASE User Drill-down System Waits tab to succinctly communicate the general overall performance levels of user specific metrics:

- System Waits
- Wait Percent by Total Waits (By Wait Class)
- Wait Percent by Time Waited (By Wait Class)
System Waits

When the Sybase ASE Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The System Waits section identifies the waits that have occurred on the Sybase ASE Server.

The table below describes the information available on the System Waits detail view. You can elect to display the internal system and scheduler events.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wait Event</td>
<td>The name of the wait event.</td>
</tr>
<tr>
<td>Wait Class</td>
<td>The type of wait, often called a wait category or class.</td>
</tr>
<tr>
<td>Wait Count</td>
<td>The number of waits that have occurred.</td>
</tr>
<tr>
<td>Percent Waits</td>
<td>The percent of waits as compared to the total number of waits.</td>
</tr>
<tr>
<td>Wait Time</td>
<td>The amount of time waited in seconds.</td>
</tr>
<tr>
<td>Percent Wait Time</td>
<td>The percent of wait time as compared to the total wait time.</td>
</tr>
</tbody>
</table>

Location [Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > System Waits tab](#)

Wait Percent by Total Waits (By Wait Class)

When the Sybase ASE Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The Wait Percent by Total Waits section graphically depicts the top waits by their percentage to all waits.

Location [Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > System Waits tab](#)

Wait Percent by Time Waited (By Wait Class)

When the Sybase ASE Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The Wait Percent by Time Waited section graphically depicts the top waits by their percentage of time waited to total time waited.
Session Waits tab

The following statistics are used on the Performance Analyst for Sybase ASE User Drill-down Locks tab to succinctly communicate the general overall performance levels of user specific metrics:

- **Session Waits**
- **Wait Percent by Total Waits (By Wait Class)**
- **Wait Percent by Time Waited (By Wait Class)**

**Session Waits**

Session waits is merely a subset of contention that is viewable at the global database level. Often it takes analysis at the session level to pinpoint the exact source of the wait that is occurring globally. Therefore, you need to become accustomed to viewing contention statistics and waits at the user process level.

When monitoring waits with respect to user sessions, there are two areas of interest:

- What HAS the user session been waiting on?
- What IS the user session waiting on?

The table below describes the information available on the Session Waits detail view. You can elect to include background process in the detail display.
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPID</td>
<td>The unique identifier for the process.</td>
</tr>
<tr>
<td>User</td>
<td>The name of the process’ user.</td>
</tr>
<tr>
<td>FID</td>
<td>The process ID of the worker process' parent.</td>
</tr>
<tr>
<td>Status</td>
<td>The current status of the process.</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database where the process is running.</td>
</tr>
<tr>
<td>Hostname</td>
<td>The client machine name where the session is running.</td>
</tr>
<tr>
<td>Program Name</td>
<td>The name of the program being run by the process.</td>
</tr>
<tr>
<td>Wait Event</td>
<td>The name of the wait event.</td>
</tr>
<tr>
<td>Wait Class</td>
<td>The type of wait, often called a wait category or class.</td>
</tr>
<tr>
<td>Waits</td>
<td>The number of waits that have occurred.</td>
</tr>
<tr>
<td>Process Waits</td>
<td>The percent of waits as compared to the total number of waits.</td>
</tr>
<tr>
<td>Wait Time (s)</td>
<td>The number of seconds the process spent waiting for this wait.</td>
</tr>
<tr>
<td>Percent Waits</td>
<td>The percent of wait time as compared to the total wait time.</td>
</tr>
</tbody>
</table>

**Location**  
Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Session Waits tab

**Metrics**  
To determine the actual wait causes currently experienced by user connections, you should drill down from the global count of users waiting, into the actual system and user wait details.

**Correction**  
If you find a problem, drill down into wait details to determine whether the waits are resource-related.

---

**Wait Percent by Total Waits (By Wait Class)**

The Wait Percent by Total Waits section graphically depicts the waits that have experienced the highest percentage of occurrences on the system.

**Location**  
Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Session Waits tab

---

**Wait Percent by Time Waited (By Wait Class)**

When the Sybase ASE Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting might mean nothing in
the overall scheme of things or it can be an indicator that a database bottleneck exists. The Session Wait Percent by Time Waited section graphically depicts the top session waits by their percentage of time waited to total time waited.

Location Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Session Waits tab

Session Details

The Sessions Detail view includes the following tabbed pages:

- **SQL tab**
- **I/O tab**
- **Object Access tab**
- **Locks/Waits**

SQL tab

The SQL tab of the Sessions Detail view offers the following information:

- **Current SQL**
- **Current Procedures**

Current SQL

This view shows a snippet of the SQL associated with the user in question.

Location Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Session Waits tab

Current Procedures

Here, in tabular format, you find the following information about the user’s current procedures:

- **Owner**
- **Object Name**
- **Object Type**
  - **Database**: The name of the database on which the procedure resides.
  - **Compile Date**: The last date on which the object was compiled.
  - **Memory (KB)**: The number of pages in the procedure cache that is currently allocated to the process. A negative number indicates that pages are being released (freed) from the process.
I/O tab

The I/O tab of the Session Detail view displays the following statistical information about the current user’s activities in a graphical display:

- Physical Reads
- Logical Reads
- Pages Read
- Pages Written
- Physical Writes
- Table Accesses (scans): The number of table accesses (scans) by the user.
- Index Accesses: The number of index accesses by the user.
- Tempdb Objects: The number of times the Tempdb was accessed by the user.

Object Access tab

The Object Access tab of the Session Detail view displays information about the current objects being accessed. Here you’ll see, in tabular format:

- Database: The name of the database
- Owner ID: The ID number assigned to the process accessing the object.
- Object Name
- Object Type: The type of object being accessed.
- Index ID
- Physical Reads: The number of physical disk reads issued against the object.
- Physical APF Reads: Number of physical Asynchronous Pre-Fetch buffers read.
- Logical Reads: The number logical reads issued against the object.

Locks/Waits

The Lock/Waits tab of the Session Details page offers statistics on:

- Waits

The following statistic, available on this tab, duplicates a statistic on the Locks tab of the Users (DBArtisan - Sybase ASE Performance Analyst) page:
Waits

When the Sybase ASE Server is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things or it can be an indicator that a database bottleneck exists. The Waits section shows processes that are currently waiting on the Sybase ASE Server.

Here you find, in tabular format, details for:

- **Login**: The logon name used by the session.
- **Database**: The name of the database the process is attached to.
- **Wait Event**: The name of the wait event.
- **Wait Class**: The type of wait, often called a wait category or class.
- **Waits**: The number of waits that have occurred.
- **Wait Time (sec)**: The amount of time waited in seconds.

Location: Sybase ASE Performance Analyst Statistics > Users (DBArtisan - Sybase ASE Performance Analyst) > Session Waits tab
OS (Sybase ASE Performance Analyst)

In many scenarios, an optimally tuned database may not perform well because there are constraints imposed by the system where the database is running. These constraints may include processes competing with the database server for resources (CPU, I/O, or Memory), a slow CPU, insufficient or slow I/O devices, and insufficient memory. The OS Statistics page of Performance Analyst lets you examine operating system metrics for the following platforms:

- AIX
- HP-UX
- Linux
- Solaris
- Unix
- Windows XP and 2000

**Note:** The statistics available on the OS page depend on the operating system platform.

**Tip:** If you magnify a graph to change back to the original size or minimize the size, close the OS Page and then reopen it again. Performance Analyst displays the graph in its original form and size.

In addition to a Home page, the OS category of Sybase ASE Performance Analyst includes the following tabbed pages:

- CPU Tab
- I/O Tab
- Memory Tab
- Network Tab
- Processes Tab
- Space Tab

**Home**

The OS home page includes the following sections:

- Bottleneck Analysis Pane
- Disk Analysis Pane
- Key Resource Usage Pane
- Memory Analysis Pane
Key Resource Usage Pane

The following ratios are used on the Performance Analyst OS home page to communicate the general overall performance levels of the operating system:

- **Disk Time**
- **Load Average**
- **Processor Time**
- **Paged Memory Used** (Windows)
- **Swap Memory Used** (AIX, HP-UX, Linux, Solaris, Unix)

**Tip:** To open the CPU tab, right-click Processor Time. To open the I/O tab, right-click Disk Time. To open the Memory tab, right-click Paged Memory Used.

**Disk Time**

The Disk Time statistic is the percentage of elapsed time that the selected disk drive/device was busy servicing read or write requests.

**Location** Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Key Resource Usage Pane

**Metrics** You should avoid consistently seeing values for this statistic greater than 90%.

**Correction** Add more disk drives and partition the files among all of the drives.

**Load Average**

The Load Average statistic represents the system load averages over the last 1, 5, and 15 minutes.

**Location** Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Key Resource Usage Pane

**Metrics** High load averages usually mean the system is being used heavily and the response time is correspondingly slow.

**Processor Time**

The Processor Time statistic indicates the percentage of time the processor is working. This counter is a primary indicator of processor activity.
Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Key Resource Usage Pane

Metrics  If your computer seems to be running sluggishly, this statistic could be displaying a high percentage.

Correction  Upgrade to a processor with a larger L2 cache, a faster processor, or install an additional processor.

**Paged Memory Used**

The Paged Memory Used statistic is the ratio of Commit Memory Bytes to the Commit Limit. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk. The commit limit is determined by the size of the paging file. As the paging file increases, so does the commit limit.

**Note:** This statistic is available for the Windows platform.

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Key Resource Usage Pane

Metrics  This value displays the current percentage value only and not an average. If the percentage of paged memory used is above 90%, you may be running out of memory.

Correction  Increase the size of page file.

**Swap Memory Used**

The Swap Memory Used statistic is the percentage of swap space currently in use.

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Key Resource Usage Pane

Metrics  If the percentage of swap memory used is above 90%, you may be running out of memory.

Correction  Increase the size of your swap files.

**Bottleneck Analysis Pane**

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Average Disk Queue Length
- Interrupts/Sec
- Network Output Queue Length/Network Queue Length
- Page Faults/Sec
Tip: To open the I/O tab, right-click any Details menu item. To open the CPU tab, right-click the Item Processor Queues Length Details menu item. To open the Network tab, right-click Network Output Queues Length.

Note: The statistics available in this section depend on the platform of operating system.

**Average Disk Queue Length**

The Average Disk Queue Length statistic is the average number of both read and write requests that were queued for the selected disk during the sample interval.

**Correction**

Some things you can do if you have problems with this statistic include: Redistribute the data on the disk with the large average disk queue to other disks. Upgrade to faster disk(s).

**Interrupts/Sec**

Interrupts/Sec is the average rate, in incidents per second, at which the processor received and serviced hardware interrupts. This value is an indirect indicator of the activity of devices that generate interrupts, such as the system clock, the mouse, disk drivers, data communication lines, network interface cards, and other peripheral devices. These devices normally interrupt the processor when they have completed a task or require attention. Normal thread execution is suspended. The system clock typically interrupts the processor every 10 milliseconds, creating a background of interrupt activity. This statistic shows the difference between the values observed in the last two samples, divided by the duration of the sample interval.
Network Output Queue Length/Network Queue Length

The Network Output Queue Length statistic is the number of threads in the processor queue.

**Note:** The name of this statistic depends on the platform of the operating system.

**Metrics** Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than 10 threads per processor is normally acceptable, dependent of the workload.

**Correction** A sustained high value in the Processor Queue Length could indicate that a processor bottleneck has developed due to threads of a process requiring more process cycles than are available. If this is the case, you should look at installing a faster (or an additional) processor.

Page Faults/Sec

The Page Faults/Sec statistic is the overall rate faulted pages are handled by the processor. It is measured in numbers of pages faulted per second. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults and soft faults.
Metrics

This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Correction

If the number of page faults remains consistently high, you can check with your Windows System Administrator for further investigation. Often, large numbers of page faults are not a problem so long as they are soft faults. However, hard faults, that require disk access, can cause delays.

### Processor Queue Length

The Processor Queue Length statistic is the number of threads in the processor queue.

**Metrics**

Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than 10 threads per processor is normally acceptable, dependent of the workload.

**Correction**

A sustained high value in the Processor Queue Length could indicate that a processor bottleneck has developed due to threads of a process requiring more process cycles than are available. If this is the case, you should look at installing a faster (or an additional) processor.

### Processor Speed

The Processor Speed statistic displays the speed of the active processor in MHz. The speed is approximate.

**Processor**

The Processor Statistic displays the type of processor currently in use, for example, GenuineIntel.
Memory Analysis Pane

The following metrics are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Available Paged Memory (Windows)
- Available Swap Memory
- Available Swap Memory (AIX, HP-UX, Linux, Solaris, Unix)
- Used Disk Space
- Total Physical Memory

Tip: To open the Memory tab, right-click any Details menu item.

Note: The statistics available in this section depend on the platform of operating system.

Available Paged Memory

The Available Paged Memory statistic shows the amount of virtual memory available for the processes.

Note: This statistic is available for the Windows platform.

Available Physical Memory

The Available Physical Memory statistic represents the amount of RAM available to all processes.
Available Swap Memory

The Available Swap Memory statistic represents the amount of virtual memory available for the processes.

Correction: If the available Available Swap Memory is less than 10% of the total Swap Memory, your system may run out of memory.

Increase the size of swap files.

Total Paged Memory/Total Swap Memory

The Total Paged Memory statistic shows the maximum amount of virtual memory available to all processes.

Note: The name of this statistic depends on the platform of the operating system.

It is recommended that this be 1½ - 3 times the amount of RAM on the system.

Total Physical Memory

The Total Physical Memory statistic shows the amount of physical memory installed on your computer.
Metrics  This is an informational metric and displays the total amount installed on the machine. Use this value with the available physical memory and paging metrics (Memory details page). If the available physical memory is very small compared to this value, and the paging activity is high, your system may be running low on memory.

Disk Analysis Pane

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Free Disk Space
- Total Disk Space
- Used Disk Space

Tip: To open the Space tab, right-click any Details menu item.

Note: The statistics available in this section depend on the platform of operating system.

Free Disk Space

The Free Disk Space statistic shows the unallocated space, in megabytes on all logical disk drives.

Correction There are many things a DBA can do to ensure that a database does not encounter a space problem due to physical space limitations, here are two: If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.

Used Disk Space

The Used Disk Space statistic shows the amount of allocated space, in megabytes on all logical disk drives.
Correction There are many things a DBA can do to ensure that a database does not encounter a space problem due to physical space limitations, here are two: If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.

Total Disk Space

Total Disk Space displays the total allocated and unallocated space, in megabytes on all logical disk drives.

Workload Analysis Pane

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Number of Logins
- Number of Processes
- Top CPU Process
- Top I/O Process
- Top Memory Process

Tip: To open the Processes tab, right-click any Details menu item.

Note: The statistics available in this section depend on the platform of operating system.

Top Memory Process

Top Memory Process shows the current process that is consuming the most amount of memory. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of
memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Workload Analysis Pane

Metrics If you are running out of memory on the system, this is a quick way to identify the top memory user. If the displayed process is using a significant portion of the total memory, it could be causing the memory issues.

Top CPU Process

Top CPU Process shows the current process that is consuming the most amount of CPU. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Workload Analysis Pane

Metrics If the amount of CPU time used by this process is close to 100% and the CPU usage is very high, this process may be the bottleneck on the server.

Correction Investigate the process further to see if it is in an inconsistent state. Also, look at minimum requirements for CPU speed for the process. You may need to upgrade your CPU.

Top I/O Process

The Top I/O Process statistic shows the current process that is consuming the most amount of CPU. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Workload Analysis Pane

Number of Logins

This statistic displays the total number of logins on the server.

Location Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Home > Workload Analysis Pane

Number of Processes

This statistic displays the total number of processes on the server.
CPU Tab

The CPU tab of the OS Detail includes the following sections:

- Context Switches/Sec
- CPU Events
- CPU Utilization
- Load Averages

The following statistics, available on this tab, are duplicates of statistics available on the Bottleneck Analysis Pane of the OS (DBArtisan - Sybase ASE Performance Analyst) Home page:

- Interrupts/Sec
- Processor Queue Length

Note: The sections available on this tab depend on the platform of operating system.

CPU Utilization

The CPU Utilization section includes the following information:

- % Privileged Time
- % User Time

% Privileged Time

The % Privileged Time statistic is the percentage of elapsed time that the process threads spent executing code in privileged mode.

Note: For Windows systems, when a Windows system service is called, the service will often run in privileged mode to gain access to system-private data. Such data is protected from access by threads executing in user mode. Calls to the system can be explicit or implicit, such as page faults or interrupts. These kernel commands, are considered privileged to keep the low-level commands executing and prevent a system freeze. Unlike some early operating systems, Windows uses process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. Some work done by Windows on behalf of the application might appear in other subsystem processes in addition to the privileged time in the process.
% User Time

The % User Time statistic is the percentage of elapsed time the processor spends in the user mode. User mode is a restricted processing mode designed for applications, environment subsystems, and integral subsystems. The alternative, privileged mode, is designed for operating system components and allows direct access to hardware and all memory. The operating system switches application threads to privileged mode to access operating system services. This counter displays the average busy time as a percentage of the sample time.

CPU Events

The CPU Events section includes the following information:

- Context Switches/Sec
- Load Averages
- System Calls/Sec

Note: The statistics available in this section depend on the platform of operating system.

Context Switches/Sec

The Context Switches/Sec section shows the combined rate at which all processors on the computer are switched from one thread to another. Context switches occur when a running thread voluntarily relinquishes the processor, is preempted by a higher priority ready thread, or switches between user-mode and privileged (kernel) mode to use an Executive or subsystem service.
OS (Sybase ASE Performance Analyst)

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > CPU Tab

Metrics  The ideal range should be between 0-10,000. GA number greater than 10,000 may indicate too many threads contending for resources.

**System Calls/Sec**

System calls are functions which require the services of the operating system. Usually they involve access to some data that users must not be permitted to corrupt or even change.

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > CPU Tab

Correction  Try to find a good ratio between the amount of time the operating system runs (fulfilling system calls and doing process scheduling), and the amount of time the application runs. Your goal should be running 60% to 75% of the time in application mode, and 25% to 40% of the time in operating system mode. If you find that the system is spending 50% of its time in each mode, then you should investigate to determine what is wrong.

**Load Averages**

The Load Average statistic represents the system load averages over the last 1, 5, and 15 minutes.

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > CPU Tab

Metrics  High load averages usually mean that the system is being used heavily and the response time is correspondingly slow.

**Processes Tab**

The Processes tab of the OS Detail page succinctly communicates the general overall performance levels of processes. The columns available in this table depend on the platform of operating system. The table below describes the information available in the table on this tab:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process</td>
<td>The name of the process.</td>
</tr>
<tr>
<td>User</td>
<td>The user of the process.</td>
</tr>
<tr>
<td>ID</td>
<td>The ID Process is the unique identifier of this process. ID Process numbers are reused, so they only identify a process for the lifetime of that process.</td>
</tr>
<tr>
<td>CPU</td>
<td>The CPU is the percentage of elapsed time that all of process threads used the processor to execute instructions.</td>
</tr>
<tr>
<td>User Mode</td>
<td>The User Mode is the percentage of elapsed time that the process threads spent executing code in user mode.</td>
</tr>
<tr>
<td>Memory WINDOWS ONLY</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory (MB)</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory</td>
<td>Memory is the percentage of the memory used of the total memory.</td>
</tr>
<tr>
<td>Active Memory</td>
<td>Active Memory is the amount of committed virtual memory, in bytes for this process. Active memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive. This counter displays the last observed value only; it is not an average.</td>
</tr>
<tr>
<td>I/O Data</td>
<td>The rate at which the process is reading and writing bytes in I/O operations. This counter counts all I/O activity generated by the process to include file, network and device I/Os.</td>
</tr>
<tr>
<td>Elapsed Time</td>
<td>The total elapsed time, in seconds, that this process has been running.</td>
</tr>
<tr>
<td>Thread Count</td>
<td>The number of threads currently active in this process. An instruction is the basic unit of execution in a processor, and a thread is the object that executes instructions. Every running process has at least one thread.</td>
</tr>
<tr>
<td>Handle Count</td>
<td>The total number of handles currently open by this process. This number is equal to the sum of the handles currently open by each thread in this process.</td>
</tr>
<tr>
<td>Priority</td>
<td>The current base priority of this process. Threads within a process can raise and lower their own base priority relative to the process' base priority.</td>
</tr>
<tr>
<td>Creating Proc ID</td>
<td>The Creating Process ID value is the Process ID of the process that created the process. The creating process may have terminated, so this value may no longer identify a running process.</td>
</tr>
</tbody>
</table>
Page Faults/Sec

Page Faults/Sec is the rate at which page faults by the threads executing in this process are occurring. A page fault occurs when a thread refers to a virtual memory page that is not in its working set in main memory. This may not cause the page to be fetched from disk if it is on the standby list and hence already in main memory, or if it is in use by another process with whom the page is shared.

Page File

Page File is the current number of kilobytes that this process has used in the paging file(s). Paging files are used to store pages of memory used by the process that are not contained in other files. Paging files are shared by all processes, and the lack of space in paging files can prevent other processes from allocating memory.

Private

Private is the current size, in kilobytes, of memory that this process has allocated that cannot be shared with other processes.

I/O Tab

The I/O tab includes the following sections:

- Average Disk Queue/Total Disk Queue
- Bytes per I/O Operation
- Disk I/O Time
- Disk Transfers/Sec
- I/O Details
- Transfer Rate

Note: The sections available on this tab depend on the platform of operating system.

I/O Details

The table below describes the information available in this section:
### Transfer Rate

The Transfer Rate section succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading</td>
<td>The average number of bytes transferred from the disk during read operations.</td>
<td>It is measured in number of KBs per second.</td>
</tr>
<tr>
<td>Writing</td>
<td>The average number of bytes transferred to the disk during write operations.</td>
<td>It is measured in number of KBs per second.</td>
</tr>
<tr>
<td>Transferred</td>
<td>The amount of time required to transfer the data between the device’s cache and the actual device media.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.
Bytes per I/O Operation

The Bytes per I/O Operation section of the OS Detail succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading</td>
<td>The average number of bytes transferred from the disk during read operations.</td>
<td>It is measured in number of bytes per second.</td>
</tr>
<tr>
<td>Writing</td>
<td>The average number of bytes transferred to the disk during write operations.</td>
<td>It is measured in number of bytes per second.</td>
</tr>
</tbody>
</table>

Average Disk Queue/Total Disk Queue

The Average Disk Queue section of the OS Detail page succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average Read Queue</td>
<td>Average Read Queue Length is the average number of read requests that were queued for a particular disk.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system.</td>
</tr>
<tr>
<td>Average Write Queue</td>
<td>Average Write Queue is the average number of write requests that were queued for a particular disk.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system. Contact your Windows System Administrator for assistance in correction these problems.</td>
</tr>
<tr>
<td>Average Queue</td>
<td>Average time in ms. to service I/O requests which for disks includes seek, rotational latency and data transfer time.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system. Contact your Unix System Administrator for assistance in correction these problems.</td>
</tr>
</tbody>
</table>

Note: The statistics available in this section depend on the platform of operating system.
Disk I/O Time

The Disk I/O Time section of the OS Detail page succinctly communicates the general overall performance levels of the disk's I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>% Disk Read Time</td>
<td>% Disk Read Time is the percentage of time during the sample interval that the disk is busy servicing read requests.</td>
<td>Use this in conjunction with the % Disk Write Time to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
<tr>
<td>% Disk Write Time</td>
<td>% Disk Write Time is the percentage of elapsed time that the selected disk drive was busy servicing write requests.</td>
<td>Use this in conjunction with the % Disk Read Time to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
<tr>
<td>% Disk Time</td>
<td>% Disk Time is the percentage of time during the sample interval that the disk is busy servicing requests.</td>
<td>Use this statistic to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.

Disk Transfers/Sec

The Disk Transfers/Sec section of the OS Detail page succinctly communicates the general overall performance levels of the disk transfers. The table below describes the statistics in this section:
OS (Sybase ASE Performance Analyst)

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reads/Sec</td>
<td>The rate of read operations on the disk.</td>
</tr>
<tr>
<td>Writes/Sec</td>
<td>The rate of write operations on the disk.</td>
</tr>
<tr>
<td>Transfers/Sec</td>
<td>The rate of transfer operations per second.</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.

Location: Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > I/O Tab

**Memory Tab**

The Memory tab of the OS Detail page includes the following sections:

- **Buffer Size**
- **Cache Efficiency**
- **Cache Size**
- **Memory Available**
- **Paging Activity**
- **Page Replacements**

The following statistic, available on this tab, duplicates a statistic available on the Bottleneck Analysis Pane of the OS (DBArtisan - Sybase ASE Performance Analyst) Home page:

- **Page Faults/Sec**

**Note:** The sections available on this tab depend on the platform of operating system.

**Paging Activity**

The Paging Activity section includes the following statistics:

- **Blocks Input/Sec**
- **Blocks Output/Sec**
- **Paged In**
- **Paged Out**
- **Pages Input/Sec**
- **Pages Output/Sec**
**Note:** The statistics available in this section depend on the platform of operating system.

### Blocks Input/Sec

The Blocks Input/sec statistic is the number of blocks sent to a block device per second.

**Location** Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

**Correction** Although it never hurts to have as much physical memory as your system can handle, here are two things you can check within your system to alleviate the memory bottleneck:
- Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle.
- Check to see if you have additional space on your disk drive that you could use to expand the size of your swap file. Normally, the bigger the initial size of your swap file, the better, in performance terms.

### Blocks Output/Sec

The Blocks Output/sec statistic is the number of blocks received from a block device per second.

**Location** Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

**Correction** Although it never hurts to have as much physical memory as your system can handle, here are two things you can check within your system to alleviate the memory bottleneck:
- Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle.
- Check to see if you have additional space on your disk drive that you could use to expand the size of your swap file. Normally, the bigger the initial size of your swap file, the better, in performance terms.

### Paged In

The number of disk block paged into core from disk which occurs when the server is experiencing a shortage of RAM. Any nonzero value indicates excessive swap activity. In any virtual memory environment, it is not uncommon to see RAM pages moved out to a swap disk. This is a special disk area in UNIX that’s reserved for holding memory pages so that the processor is capable of addressing RAM in excess of its full capability. While page-out of operations are a normal part of any server’s operations, page-in operations indicate that the real amount of available RAM has been exceeded and that additional RAM pages are required on the server.
Correction: High values indicate the possible need to increase the amount of RAM on the system.

Paged Out

The number of disk block paged out of core from disk. In any virtual memory environment, it is not uncommon to see RAM pages moved out to a swap disk. This is a special disk area in UNIX that’s reserved for holding memory pages so that the processor is capable of addressing RAM in excess of its full capability. While page-out of operations are a normal part of any server’s operations, page-in operations indicate that the real amount of available RAM has been exceeded and that additional RAM pages are required on the server.

Pages Input/Sec

The Pages Input/Sec statistic is the number of pages read from disk to resolve hard page faults. Hard page faults occur when a process requires code or data that is not in its working set or elsewhere in physical memory, and must be retrieved from disk.

Correction: Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Pages Output/Sec

This metric is the number of pages written to disk to free up space in physical memory. Pages are written back to disk only if they are changed in physical memory. A high rate of pages output might indicate a memory shortage.
Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

Metrics  Windows NT writes more pages back to disk to free up space when low in physical memory. This counter counts numbers of pages, and can be compared to other counts of pages, without conversion. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Correction  Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Memory Available

The Memory Available section of the OS Detail page succinctly communicates the general overall performance levels of the server’s memory. The statistics available in this section depend on the platform of operating system. The table below describes these statistics:
<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
<th>Correction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical Memory</td>
<td>The Physical Memory statistic is the amount of committed virtual memory, in megabytes. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk.</td>
<td>This counter displays the last observed value only and not an average.</td>
<td>N/A</td>
</tr>
<tr>
<td>Physical</td>
<td>The Physical statistic is the total physical memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Paged Memory</td>
<td>The Paged Memory statistic is the amount of committed virtual memory, in bytes. Used Memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive.</td>
<td>This counter displays the last observed value only; it is not an average.</td>
<td>N/A</td>
</tr>
<tr>
<td>Swap Memory</td>
<td>The Swap Memory statistic is the free, unreserved swap space.</td>
<td>N/A</td>
<td>Increase the size of your swap file or add additional files if you consistently see a shortage of free, unreserved swap space.</td>
</tr>
<tr>
<td>Swap</td>
<td>The Swap statistic is the total swap memory being used.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Total Physical</td>
<td>The Total Physical statistic is the total physical memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Total Swap</td>
<td>The Total Swap statistic is the total swap memory available.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Swap-ins</td>
<td>The number of memory pages paged in from swapspace.</td>
<td>N/A</td>
<td>If the system is consistently low on free memory (over a 30 second average), the memory scheduler will start to swap out processes. Increase the size of your swap file or add additional files.</td>
</tr>
<tr>
<td>Swap-outs</td>
<td>The number of memory pages paged in from swapspace.</td>
<td>N/A</td>
<td>If the system is consistently low on free memory (over a 30 second average), the memory scheduler will start to swap out processes. Increase the size of your swap file or add additional files.</td>
</tr>
</tbody>
</table>
Buffers

The Buffers statistic represents the amount of buffers used by the kernel in kilobytes.

Page Faults/Sec

The Page Faults/Sec statistic is the overall rate faulted pages are handled by the processor. It is measured in numbers of pages faulted per second. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults and soft faults.

This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

If the number of page faults remains consistently high, you can check with your Windows System Administrator for further investigation. Often, large numbers of page faults are not a problem so long as they are soft faults. However, hard faults, that require disk access, can cause delays.

Buffer Size

The Buffer Size statistic represents the amount of cache used by the kernel in kilobytes.

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

Cache Size

The Cache Size statistic represents the amount of cache used by the kernel in kilobytes.

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

Page Replacements

The following statistics are available in this section:

- Memory Freed (Pages/sec)
- Clock Algorithm Scans (Pages/sec)

Memory Freed (Pages/sec)

Freed or destroyed (Kb/s).

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

Clock Algorithm Scans (Pages/sec)

The VMM uses a technique known as the clock algorithm to select pages to be replaced. This technique takes advantage of a referenced bit for each page as an indication of what pages have been recently used (referenced). When the page-stealer routine is called, it cycles through the PFT, examining each page's referenced bit.
Cache Efficiency

The Cache Efficiency section of the Memory tab succinctly communicates the general overall performance levels of the server's memory. The following statistics are available in this section:

- **Copy Read Hits %**
- **Data Map Hits %**
- **MDL Read Hits %**
- **Pin Read Hits %**

### Copy Read Hits %

The Copy Read Hits % statistic is the percentage of cache copy read requests that hit the cache and does not require a disk read to provide access to the page in the cache.

**Metrics**

When the page is pinned in the memory, the page's physical address in the file system cache will not be altered. A copy read is a file read operation where a page in the cache is copied to the application's buffer. Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

**Correction**

Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

### Data Map Hits %

The Data Map Hits % statistic is the percentage of data maps in the file system cache that could be resolved without having to retrieve a page from the disk.
OS (Sybase ASE Performance Analyst)

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

Metrics Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

Correction Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

**MDL Read Hits %**

The MDL Read Hits % statistic is the percentage of Memory Descriptor List Read requests to the file system cache that hit the cache and does not require disk access to provide memory access to the pages in the cache.

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

Metrics Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

Correction Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

**Pin Read Hits %**

The Pin Read Hits % statistic is the percentage of pin read requests that hit the file system cache and does not require a disk read in order to provide access to the page in the file system cache.

Location  Sybase ASE Performance Analyst Statistics > OS (DBArtisan - Sybase ASE Performance Analyst) > Memory Tab

Metrics Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

Correction Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

**Space Tab**

The Space tab of the OS Detail page includes the following sections:

- Device Summary
- Device Detail
Disk Space Free

The Disk Space Free metric displays the amount of free disk space in megabytes.

Disk Space Detail

The Disk Space Detail section of the Space tab succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition</td>
<td>The drive letter of the disk.</td>
</tr>
<tr>
<td>Local Filesystem</td>
<td>The name of the file system.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of file system.</td>
</tr>
<tr>
<td>Total Space</td>
<td>Total size of the disk/device’s capacity expressed in MBs.</td>
</tr>
<tr>
<td>Used Space</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free Space</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
<tr>
<td>Capacity</td>
<td>The percentage of space used on the device.</td>
</tr>
<tr>
<td>Mounted On</td>
<td>The mount point of the device.</td>
</tr>
</tbody>
</table>

Device Summary

The Device Summary section of the Space tab displays a bar chart for all devices. The Device Summary section succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Used</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
</tbody>
</table>
Device Detail

The Device Detail section of the Space tab succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition</td>
<td>The drive letter of the disk.</td>
</tr>
<tr>
<td>Local Filesystem</td>
<td>The name of the file system.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of file system.</td>
</tr>
<tr>
<td>Total Space</td>
<td>Total size of the disk/device's capacity expressed in MBs.</td>
</tr>
<tr>
<td>Used Space</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free Space</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
<tr>
<td>Capacity</td>
<td>The percentage of space used on the device.</td>
</tr>
<tr>
<td>Mounted On</td>
<td>The mount point of the device.</td>
</tr>
</tbody>
</table>

Note: The statistics available in this section depend on the platform of operating system.

Network Tab

The Network tab of the OS Detail page succinctly communicates the general overall performance levels of the server’s networking. The Network tab of the OS Detail page includes the following sections:

- Network Details
- Packet Collisions
- Packet Discards
- Packet Errors
- Transmission Rate
- Transmission Rate (Bytes)
- Transmission Queue Length
**Note:** The sections available on this tab depend on the platform of operating system.

## Network Details

The statistics available in this section depend on the platform of operating system. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network Interface</td>
<td>The name of network interface.</td>
</tr>
<tr>
<td>INET Address/Address</td>
<td>The IP address assigned to the network interface.</td>
</tr>
<tr>
<td>Pkts Sent/Sec</td>
<td>The number of packets sent per second.</td>
</tr>
<tr>
<td>Pkts Received/Sec</td>
<td>The number of packets received per second.</td>
</tr>
<tr>
<td>Sent (KB/Sec)</td>
<td>The number of bytes sent per second.</td>
</tr>
<tr>
<td>Received (KB/Sec)</td>
<td>The number of bytes received per second.</td>
</tr>
<tr>
<td>Out Pkts Discarded</td>
<td>The number of outbound packets discarded.</td>
</tr>
<tr>
<td>In Pkts Discarded</td>
<td>The number of inbound packets discarded.</td>
</tr>
<tr>
<td>Out Pkt Errors</td>
<td>The number of outbound packet errors.</td>
</tr>
<tr>
<td>In Pkt Errors</td>
<td>The number of inbound packet errors.</td>
</tr>
<tr>
<td>Queue Length</td>
<td>The queue length.</td>
</tr>
<tr>
<td>Collisions</td>
<td>The number of collisions.</td>
</tr>
<tr>
<td>Packets Discarded</td>
<td>The number of packets discarded.</td>
</tr>
</tbody>
</table>

Location: [Sybase ASE Performance Analyst Statistics](#) > [OS (DBArtisan - Sybase ASE Performance Analyst)](#) > [Network Tab](#)

## Transmission Rate

The Transmission Rate section of the Network tab succinctly communicates the packet transmission rate. The following statistics are available in this section:

- Packets Received/Sec
- Packets Sent/Sec

## Packets Sent/Sec

The Packets Sent/Sec statistic is the number of packets sent over each network adapter per second.
Packets Received/Sec

The Packets Received/Sec statistic is the number of packets received over each network adapter per second.

Transmission Rate (Bytes)

The Transmission Rate (Bytes) section of the Network tab succinctly communicates the packet transmission rate. The following statistics are available in this section:

- Received (KB/Sec)
- Sent (KB/Sec)

Sent (KB/Sec)

The Sent (KB/Sec) statistic is the rate at which bytes are sent over each network adapter including framing characters.

Received (KB/Sec)

The Received (KB/Sec) statistic is the rate at which bytes are received over each network adapter, including framing characters.

Transmission Queue Length

The number of pending outgoing packets on either the software transmit queue or the hardware transmit queue.
Packet Collisions

A collision occurs when two devices on the network sense that the network is idle and end up trying to send data at the same time. Some collisions are normal on a repeated network, but excess collisions can cause serious performance problems.

Correction Contact your network administrator if there is high rate of persistent Packet Collisions.

Packet Discards

The Packet Discards section of the Network tab succinctly communicates the packet discard rate. The following statistics are available in this section:

- **Inbound Packets Discarded**
- **Outbound Packets Discarded**
- **Packet Discards**

Outbound Packets Discarded

The Outbound Packets Discarded statistic is the number of outbound packets that were discarded even though no errors had been detected to prevent from being transmitted.

Correction A possible reason for discarding such a packet could be to free up buffer space.

Inbound Packets Discarded

Received Packets Discarded is the number of received packets that were discarded even though no errors had been detected to prevent from being transmitted.

Correction A possible reason for discarding such a packet could be to free up buffer space.

Packet Discards

The Packet Discards statistic represents the number of network packets discarded.
Correction Contact your network administrator if there is high rate of persistent packet discards.

Packet Errors

The Packet Errors section of the Network tab succinctly communicates the packet error rate. The following statistics are available in this section:

- **Inbound Packet Errors**
- **Outbound Packet Errors**

Outbound Packet Errors

The Outbound Packet Errors statistic is the outbound packets that contained errors preventing them from being deliverable to a higher-layer protocol.

Inbound Packet Errors

The Packets Received Errors statistic is the received packets that contained errors preventing them from being deliverable to a higher-layer protocol.
Top SQL Statistics (Sybase ASE Performance Analyst)

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements or stored procedures can drag an otherwise well-configured database down in terms of user response times.

Before you can identify problem SQL in your database, you have to ask the question of what ‘bad SQL’ is. What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every SQL Server professional’s satisfaction. The Top SQL results grid displays the top SQL statements across various performance categories.

The SQL Details tab of the Top SQL view presents information as follows:

- **Active SQL Results**
- **Selected SQL Text**

**Metrics**

When you begin to look for inefficient SQL in a database, there are two primary questions you need to answer:

- What has been the worst SQL that’s historically been run in my database?
- What is the worst SQL that’s running right now in my database?

When correction a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It may be that the query is in an inefficient loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.

**Active SQL Results**

The Active SQL results section displays the following information in grid format:

- **SQL Text**: A snippet of the full SQL statement. Clicking on the statement will cause the full statement to be presented in the Selected SQL Text grid.

- **Database**: The name of the database.

- **SPID**: The process ID.

- **CpuTime**: The accumulated CPU time for the statement.

- **Wait Time**: The time the process has been waiting to be serviced, in milliseconds. A value of zero indicates there was no waiting.
- **Memory Usage (KB):** The number of pages in the procedure cache that is currently allocated to the process. A negative number indicates that pages are being released (freed) from the process.

- **Physical Reads:** The current cumulative number of physical disk reads issued by the process.

- **Logical Reads:** The current cumulative number logical reads issued by the process.

- **Pages Modified:** The number of pages that were modified by the process.

- **Packets Received**

- **Packets Sent**

- **Start Time:** The date/time when the statement was first executed.

- **Batch ID**

**Selected SQL Text**

In this section of SQL details, you see the fully expanded SQL statement that you highlighted in the Active SQL Results grid. By clicking Explain SQL you open the Explain Plan with its ISQL window.
Performance Analyst for IBM DB2 for Linux, Unix and Windows Tutorial

Embarcadero Performance Analyst provides key insight into the complex world of database performance. Running inside the Embarcadero DBArtisan console, or standalone in a Web browser, Performance Analyst helps you pinpoint performance problems that threaten a database’s availability or response times. The powerful analysis facilities will satisfy advanced experts, yet novices will find Performance Analyst’s interface easy to use and the expert help a welcome aid to troubleshooting difficult performance issues.

About This Performance Analyst for IBM DB2 Tutorial

This tutorial is intended to help you get started with Embarcadero Performance Analyst. After completion of this tutorial, you will have the foundation you need to explore the many features and benefits of Performance Analyst. You will have learned how to accurately monitor your database using the most popular performance methodologies in use today. You will know how to drill down into the many layers of database performance and also be able to locate performance issues in your database in a fast and effective manner. Finally, you’ll understand how to fix performance problems using the integration that exists between Performance Analyst and Embarcadero DBArtisan.

This tutorial is divided into 8 sections.

- Session 1: Getting Started With Performance Analyst for DB2
- Session 2: Using Ratio-based Performance
- Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for DB2
- Session 4: Using Workload Performance Analysis
- Session 5: Using SQL Performance Analysis
- Session 6: Using Operating System Performance Analysis
- Session 7: Identifying and Getting Help With Performance Problems
- Session 8: Fixing Performance Problems Using Performance Analyst for DB2

You can use this basic tutorial as a roadmap of product highlights.

After starting this tutorial, you can select Help from the menu to find many additional resources that complement and build on many of the activities shown in this brief tutorial.

Topics

- Session 1: Getting Started With Performance Analyst for DB2
- Session 2: Using Ratio-based Performance

Session 1: Getting Started With Performance Analyst for DB2

Download and Install

You can obtain the latest version of Performance Analyst by downloading the DBArtisan software from the Embarcadero Web site at http://www.embarcadero.com/downloads/downloaddbartisan.asp. Performance Analyst runs fully contained within DBArtisan so you will need the DBArtisan product to use Performance Analyst (although Performance Analyst can also run in standalone fashion within a Microsoft Internet Explorer Web browser).

Click Download, and follow the steps indicated. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for 14 days. After that time, a permanent license is needed.

Overview for Performance Analyst for DB2

When DBArtisan is connected to an DB2 database, you can open Performance Analyst two ways:

1. On the toolbar, click the Performance Analyst icon.

2. On Utilities menu, select Performance Analyst.

DBArtisan opens Performance Analyst.

DB2 requires that certain monitor switches be turned on for collecting various performance metrics. When Performance Analyst is first invoked, you will be prompted to turn on the monitor switches. Also, you can increase or decrease the size of the monitor heap depending on the activity of your database.

If you do not want to see this dialog each time you start Performance Analyst, you can check the "Save these settings as default" check box.

Product Navigation

Navigating through Performance Analyst is easily accomplished through two main mechanisms:

1. The main Performance Analyst toolbar contains buttons and drop-down menus that invoke the performance analysis main views and drill-downs within the product as well as frequently used actions like Refresh and Performance Threshold Customizations.

2. Positioning the mouse pointer on any area within Performance Analyst and right-clicking brings up a navigation menu that allows you to easily move between any
of the main Performance Analyst home pages and drill-down views. The right mouse menu also contains context-sensitive options like drilling down further into a particular statistic, copying the display to a text file, and more.

Proceed to Session 2: Using Ratio-based Performance

Session 2: Using Ratio-based Performance

Ratio-based analysis has been around for many years, and used to be the only technique database administrators used when they were called on to diagnose the cause of a database slowdown. Performance ratios are very good roll-up mechanisms for busy DBAs, making possible the analysis-at-a-glance approach, however ratios must be computed correctly for them to be meaningful. Key ratios in Performance Analyst are calculated using delta statistics, which is superior to computing ratios with cumulative values. Delta statistics, which are values derived by using the before and after measures in each statistical refresh done in Performance Analyst, lets you see changes in performance metrics that would otherwise be invisible if cumulative statistics were used. Performance Analyst makes it easy to see the ratios that are computed with delta statistics vs. cumulative. A triangle symbol denotes a delta-based statistic, while square symbols represent a cumulative-based measure.

Ratio-based analysis is available for all performance categories (memory, etc.) where ratios can assist in determining the performance level of a database. For example, if you would like to see memory-specific ratios, on the Performance Analyst toolbar click Memory. Performance Analyst displays the Memory home page that showcases all important memory-related ratios.

Obtaining Detail Information for a Ratio Using Performance Analyst for DB2

A ratio gives you a global picture for a particular performance measure. However, you often need more information regarding a statistical measure so you can make an informed decision. Performance Analyst has easy-to-use drill down features that make obtaining detailed information for various ratios a breeze.

For example, to view more information for the Buffer Cache Hit Ratio statistic, do the following:

1. On either the main Home page or the I/O home page, locate the Buffer Pool Hit Ratio statistic.

2. Position the pointer over the statistic.

The pointer changes to a hand symbol.

3. Double-click the left mouse button.

Performance Analyst opens the Buffer Cache tab of the memory drill down view.
Session 3: Using Bottleneck/wait-based Performance Analysis in Performance Analyst for DB2

When a DB2 database is up and running, every connected process is either busy doing work or waiting to perform work. A process that is waiting may mean nothing in the overall scheme of things, or it can be an indicator that a database bottleneck exists. Bottleneck analysis is a valid method of measuring performance because it helps you track where a database and user sessions have been spending their time. If lock contentions or heavy table-scan activity has been dragging a database’s performance down, you can use bottleneck analysis to confirm the actual root cause.

Performance Analyst uses several key areas of DB2 metrics to form its bottleneck analysis. These areas are usually the main sources of performance drag on the databases.

Performance Analyst prominently displays bottleneck analysis on every performance home page. On the main home page, you will see a summary of all key bottlenecks threatening the database. You can also see specific bottlenecks for memory, I/O, space, objects, and users by navigating to each home page and viewing the Bottleneck Analysis section for that home page.

For example, to see bottlenecks that specifically relate to user applications, follow these steps:

1. Click the Users Performance Analyst toolbar button
2. Locate the Bottleneck Analysis section at the lower-left portion of the screen

The Users Bottleneck Analysis section shows the top bottlenecked applications, concurrency issues, and bottleneck activity count.

Obtaining Detail on System Bottlenecks

You can easily obtain more information regarding global bottlenecks that are plaguing a database by drilling down into a particular bottleneck metric. For example, if you would like to see more data regarding the current top concurrency bottlenecks, do the following:

1. Open the Performance Analyst main Home page.
2. Double-click the Concurrency area in the Bottlenecks section to be taken to the Lock Waits drill-down section.

Performance Analyst opens the System Waits view.

3. Or right-click anywhere in Performance Analyst, point to Users, and then click Lock Waits.

Performance Analyst opens the System Waits view.

The Lock Waits view displays critical details regarding all the lock wait events that DB2 has recorded. You can easily see what applications are waiting on locks and the average lock wait times for all applications.

**Note:** If you would like to see an expanded view of the Lock Waits grid shown on the top of the Lock Waits view, click the Expand button located at the top right corner of the section. All section views in Performance Analyst can be maximized/minimized using this control.

### Viewing Detail for Application Bottlenecks

Not only can you obtain detail information for system bottlenecks, but you can also use Performance Analyst to get drill-down information regarding the locks held by and waited on by applications.

To see more information regarding application locks, do the following:

1. Open the Performance Analyst main Home page.
2. Double-click the Concurrency Bottlenecks area to be taken to the Lock Waits drill-down view.

Performance Analyst opens the Lock Waits tab.

3. Or right-click anywhere in Performance Analyst, point to Users, and then click Locks.

Once on the Locks drill-down view, you can view the details for locks held and waited on by an application details by following these steps:

1. Examine the Application Details grid
2. Select an application that appears to be experiencing lock waits problem

You will see details on the locks held by, and the locks waited on, by the selected application. You can get further details on the application that is holding the locks by navigating to the Attributes drill-down and selecting the appropriate Application ID.

Proceed to [Session 4: Using Workload Performance Analysis](#)
Session 4: Using Workload Performance Analysis

Key ratios give you a global perspective on database activity. Bottleneck analysis gives you insight into things that are holding up user activity and throughput. But another technique is necessary if a database professional is to really get a handle on what’s occurring inside a badly performing database.

Workload analysis involves the investigation of two critical areas of a database’s performance:

- Application resource consumption and activity
- SQL execution

Without looking at these two key performance categories, you can miss a lot of what could be responsible for perceived performance problems. When performance on a database takes a sudden nosedive, it is not uncommon to find one or two sessions that are causing the bulk of the workload. Finding these processes can be easily accomplished by viewing session metadata coupled with resource consumption and statistical execution statistics.

Pinpointing Top Resource Consumers

Performance Analyst identifies top resource consumers in a couple of different ways. On the main home page, Performance Analyst highlights the top resource consumers across lock usage, CPU usage, and I/O usage. The percentage used across all statistical categories are displayed so a DBA can immediately pinpoint a session that is using all or most of a particular resource. The top resource sessions are also displayed on the memory, I/O, and other home pages as well with a listing for the top sessions for that category (for example, the top IO consumers appear on the I/O home page, etc.).

Getting Workload Details Using Performance Analyst for DB2

Performance Analyst offers several details on top resource applications in addition to the summaries provided on each home page. A detailed and flexible top applications view lets you view a summary of all the major resource applications on the database as well as every critical detail regarding each application connected to the database.

Further drill-downs are available that highlights specific details regarding each application’s activities and submitted SQL. To see detailed information regarding an application identified in one of Performance Analyst’s Workload Analysis sections, do the following:

1. In a Workload Analysis display, position the pointer over one of the processes.
2. Double-click the process or right-click, and then select Details.
If you want like to see all key workload analysis metadata for sessions, do the following:

1. On the toolbar, click the Top Sessions button.
2. Or right-click anywhere in Performance Analyst, point to Users, and then click Top Sessions.

Session 5: Using SQL Performance Analysis

SQL-based performance analysis is really a subset of Workload Analysis. Understanding current and historical SQL execution patterns lets you to have the second set of data points necessary to properly perform workload analysis. You may find that optimizing SQL code produces some of the best performance-enhancing boosts available for a database.

Proceed to Understanding SQL Activity
Understanding SQL Activity

Performance Analyst offers plenty of insight into SQL performance and execution patterns. Each one of the home pages depicts the current levels of SQL activity as determined by a variety of different metrics for that performance category. For example, Performance Analyst might show that rows reads account for 75% of all SQL statement I/O on the database.

Getting Details on Top SQL

Getting details on identified SQL statements is easy in Performance Analyst. For example, if you would like to see further information on a SQL statement identified on the Performance Analyst Home page, do the following:

1. In the SQL Analysis section, position the pointer over Hash Values.
2. Double-click or right-click, and then select Details.

Performance Analyst opens the Top SQL summary page that shows a breakdown of all top SQL statements along with their execution statistics.

If you would like to see the full SQL text of a SQL statement, do the following:

1. In the Top SQL Details section, double-click a statement.

Performance Analyst opens the SQL Details tab of the Top SQL view to display the entire SQL statement and the execution metrics. While on this pane, you can also perform an EXPLAIN of the SQL statement and examine its access path information.

Note: To automatically tune a problem SQL statement if you have Embarcadero SQL Tuner installed on your workstation, do the following:

2. On the SQL Details tab, select a problem statement, and then click the Tune SQL button.

SQL Tuner opens and you can begin a tuning session.

Proceed to Session 6: Using Operating System Performance Analysis
Session 6: Using Operating System Performance Analysis

In many scenarios, an optimally tuned database may not perform well because there are constraints imposed by the system where the database is running. These constraints may include processes competing with the database server for resources (CPU, I/O or Memory), a slow CPU, insufficient I/O devices, and insufficient memory. Performance Analyst allows you to examine the relevant operating system metrics for DB2.

To view the operating system metrics of the machine hosting the DB2 server you are monitoring, do the following:

1. Click the OS Performance Analyst toolbar button.

OR

2. Navigate to the OS Home Page by going to OS, and then Home.

**Note:** The first time you invoke the OS feature you will be prompted for an operating system login. Please specify the correct operating system, host name, username and password, and protocol.

The Operating System home page has been designed in a similar fashion as the datasource home page. On this page you can see the pertinent operating system metrics displayed in five quadrants broken down into the following categories:

- Resource Usage
- Memory Analysis
- Disk Analysis
- Workload Analysis
- Bottleneck Analysis

**Obtaining Details on the Operating System**

You can easily obtain more information regarding operating system problems that are degrading database performance by drilling down into a particular analysis quadrant. For example if you’d like to see more information regarding the processes running on the host machine, do the following:

1. Navigate to the Performance Analyst Operating System home page.

2. Double-click the Top Memory Process in the Workload Analysis quadrant.

Performance Analyst opens the Processes detail view.

OR
3. Right-click anywhere in Performance Analyst and select the Navigate to, OS, and then Processes.

The Processes detail tab shows all the processes on the host machine. From this view you can easily determine which processes are showing high marks in I/O or CPU, for example, by simply double clicking on the column headers and sorting the processes in ascending or descending order.

Proceed to Session 7: Identifying and Getting Help With Performance Problems
Session 7: Identifying and Getting Help With Performance Problems

You do not need to be an advanced expert in performance tuning to spot trouble in a database if you use Performance Analyst. There are a number of mechanisms in the tool that help you quickly locate areas of concern within a database.

Using the Alarm Log

Performance Analyst has a central and flexible alarm log that lists every performance violation found in all monitored databases. Unlike some products that only show you alarms for a particular database, Performance Analyst lists all alarms for each database you are monitoring in one central log so you can see every problem in one place. To view the Performance Analyst Alarm log, do the following:

1. On the toolbar, click the Alarms button.

Once in the Alarm log, you can perform a number of actions including:

- Selecting an alarm and viewing the application page that shows details regarding the metric in violation.
- Filtering the types of alarms shown through the Options dialog.
- Clearing all current alarms.
- Copying or saving the Alarm log into a different format.

To select any of these options, do the following:

1. Position the pointer over any area of the Alarm Log.
2. In the shortcut menu, select an option.

Recognizing Performance Violations

Performance Analyst makes it easy to visually pinpoint performance violations in a database. Any statistic that does not conform to your predefined performance standards is colorized in any view that it appears so you can easily see potential troublespots.

The colors used to highlight a particular performance violation depend on the severity of the problem. Performance Analyst uses several layers of performance standards/threshold violations with each layer being represented by a different color. You can control everything regarding threshold violations, including how thresholds are determined, their color representation in Performance Analyst’s display, and more by using the Threshold Template feature of Performance Analyst.

How can Performance Analyst inform you of performance violations in your database if you minimize the product to your desktop and are working on other things? Even if Performance Analyst isn’t right in front of you, it can still let you know that a problem has...
been found in your database through the systray alarm icon. When Performance Analyst detects a problem in one of your databases, one of the things the product does is enable an alarm icon in your workstation’s systray area that communicates the presence of alarms in your database. So even if the Performance Analyst interface isn’t in sight, the product can let you know that something in your database requires attention.

Creating Threshold Templates

How does Performance Analyst know what to signal as a problem in a database? It uses predefined performance standards that you define and enforce. All of this is accomplished by using Performance Analyst’s Threshold templates. A template is a set of performance metrics and their thresholds that can be reused to enforce performance standards across any number of databases. Embarcadero provides a default performance template that contains nearly all of the most-watched performance statistics so you can begin monitoring with confidence right out of the box. However, you can create your own Threshold templates so you only are alerted to performance violations that are important to you and your particular environment.

To view or create Threshold templates, do the following:

1. On the toolbar, click the Thresholds button.

Performance Analyst opens the Threshold maintenance dialog.

The Threshold Template Properties dialog lets you select the options to add or edit templates, as well as other maintenance options. For example, you can copy the original Embarcadero Threshold template and modify it to fit your own needs. You can control what statistics are sampled for performance violations as well as the levels of severity you would like reported. Once you are satisfied with your template, you can save it and then apply it to one or more datasources in one action to immediately begin enforcing your performance standards.

Getting Help With Performance Problems

As databases become more complex, so do the problems that plague them. Knowing what to do for a particular performance problem can be hard in some cases, but Performance Analyst helps by providing a complete set of expert help that you can use as a guide when performance problems occur. To obtain expert help for any statistic shown in Performance Analyst, do the following:

1. Position the pointer over a statistic that you need help with.

2. Right-click and select Help.

The Expert Help gives you a general description of the statistic, the range of values that are considered optimal, and some suggestions on how to fix a problem situation. Expert help can also be invoked for any of the Ratio, Bottleneck, SQL, or Workload Analysis sections shown on every home page by clicking on the help icon for that section, which is located at the top right corner of the section.

Proceed to Session 8: Fixing Performance Problems Using Performance Analyst for DB2
Session 8: Fixing Performance Problems Using Performance Analyst for DB2

Finding performance problems is one thing, but fixing them is another. Many performance monitors point out a particular problem in a database, but then offer no way to actually correct the situation. Such is not the case with Performance Analyst. Because of its tight integration with DBArtisan, certain problems found in Performance Analyst can be visually corrected by DBArtisan.

If a DB2 tablespace is about to run out of free space, Performance Analyst can issue an alarm that a space shortage exists. Once the space problem has been identified, do the following:

1. On the Space home page toolbar, click the Space button.
2. In the Space Analyst grid, right-click a tablespace, and then select Manage with DBArtisan.

You will then be taken to DBArtisan’s Tablespace Editor where you can perform corrective actions, such as adding new containers to the tablespace, or resizing the tablespace’s existing container(s).
IBM DB2 (W/U/L) Performance Analyst statistics

This section includes expert help for all DB2 categories and statistics in the Embarcadero Performance Analyst views and pages. This help is divided into the following sections:

- Home View (DB2 LUW Performance Analyst)
- Memory View (DB2 LUW Performance Analyst)
- I/O
- Space View (DB2 LUW Performance Analyst)
- Users View (DB2 LUW Performance Analyst)
- Cfg (Database Configuration)
- Instance View (DB2 LUW Performance Analyst)
- OS View (DB2 LUW Performance Analyst)
- Top SQL View (DB2 LUW Performance Analyst)

Topics

- Home View (DB2 LUW Performance Analyst)
- Memory View (DB2 LUW Performance Analyst)
- Space View (DB2 LUW Performance Analyst)
- Users View (DB2 LUW Performance Analyst)
- Cfg (Database Configuration)
- History View (DB2 LUW Performance Analyst)
- Instance View (DB2 LUW Performance Analyst)
- OS View (DB2 LUW Performance Analyst)
- Top SQL View (DB2 LUW Performance Analyst)
Home View (DB2 LUW Performance Analyst)

The Embarcadero Performance Analyst Home view lets you review availability and overall performance of all monitored databases from a single window. Statistics on the Home view are organized into the following categories:

- Key Ratio Analysis Pane
- Bottleneck Analysis Pane
- SQL Analysis Pane
- Storage Analysis Pane
- Workload Analysis Pane

Key Ratio Analysis Pane

Database performance analysts typically use ratio-based or wait/bottleneck-based methods for examining the performance levels. Ratio-based analysis involves examining a number of key database ratios that indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for at-a-glance performance analysis. Many DBAs have large database farms to contend with and cannot spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are certainly many opinions as to what rules to follow, there are some standards that should always be adhered to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that a DBA will examine come from the DB2 Snapshot Monitor. The snapshot monitor returns metrics for the Instance and particular databases since the start of monitoring. Some metrics are cumulative (e.g., counters) and others are instantaneous (e.g., gauges).

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each SQL Server's individual 'personality' with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following ratios are used on the Performance Analyst Home page to succinctly communicate the general overall performance levels of the monitored database:

- Efficiency:
- **Buffer Pool Hit Ratio**
- **Catalog Cache Hit Ratio**
- **Package Cache Hit Ratio**
- **Shared Workspace Hit Ratio**

- **Resource Utilization:**
  - **Database Heap Utilization**
  - **Log Space Utilization**
  - **Lock List Utilization**
  - **Shared Sort Memory Utilization**

**Buffer Pool Hit Ratio**

The DB2 database server reads and updates all data from a bufferpool because memory access is much faster than disk access. Data is copied from disk to a bufferpool as needed by the applications using the database. When the server needs to read/write data and the data is already in the bufferpool, no disk access is required. However, if the data is not in the bufferpool, it needs to be read from the disk, which is significantly slower process.

The buffer pool hit ratio indicates the percentage of time that the database server did not need to load a page to service the request for a page. The calculation takes into account all the index and data pages that were requested.
Metrics  Avoiding disk I/O is the main issue when you try to improve the performance tuning. A high buffer pool hit ratio is desirable because it indicates a lower frequency of synchronous disk I/O. A database where data is accessed uniformly from very large tables will have a poor hit ratio. There is little you can do to improve the performance in such cases.

Correction  The buffer pool hit ratio on the database Home page is the overall hit ratio of the database. First, drill down to the bufferpool level and check the individual buffer pool hit ratios to identify the elements that may require tuning. Increasing the bufferpool size generally improves the buffer pool hit ratio. You can use one of the following methods to increase the bufferpool size depending on the layout of the data:

- If the tablespaces using the bufferpool have tables and indexes on them, increase the bufferpool size incrementally until the index page hit ratio stops increasing for that bufferpool. You will not usually get any benefit increasing the bufferpool size after you reach that point.
- If the tablespaces associated with the bufferpool have only indexes on them, increase the bufferpool size until the index page hit ratio stops increasing.
- If the tablespaces associated with the bufferpool have only data on them, increase the bufferpool size until the data page hit ratio stops increasing.

One general design guideline is to try and use different tablespaces for indexes and tables and associate different bufferpools with them. This generally improves performance and makes bufferpool tuning much easier.

Catalog Cache Hit Ratio

Catalog cache is used to cache the following types of catalog information:

- Metadata for tables, views, and aliases.
- Database authorization information that is used to check authorization when performing operations like CONNECT, LOAD, CREATE, BIND, and so on.
- Execute privileges for user-defined functions and stored procedures.

When a database operation accesses catalog information, it inserts this information into the catalog cache so operations accessing the same information can read it from the cache and avoid disk reads. The catalog cache hit ratio indicates how well the catalog cache avoids accesses to the catalog.
Location

Metrics

A high catalog cache hit ratio (> 80%) indicates that the catalog cache is working well. A smaller ratio can indicate that this parameter needs tuning. You may see a smaller ratio immediately following the first connection to the database and execution of DDL/DCL statements since these require heavy catalog accesses.

Correction

If the catalog cache hit ratio is consistently small, increase the database configuration parameter catalogcache_sz. When you increase this value, pause to consider whether it would be more effective to allocate the extra memory you are reserving to another purpose such as package cache or bufferpools. In a partitioned database environment, make the catalogcache_sz larger on the catalog partition than on other partitions because the catalog information required for all partitions will go through this partition. When tuning this parameter, it is advisable to monitor changes to the database catalog via DDL statements. During the execution of DDL statements, there may be a large drop in the catalog cache hit ratio due to invalidation of the cached data.

Package Cache Hit Ratio

Embarcadero DBArtisan’s Database Manager caches the sections for frequently used dynamic and static SQL statements in the package cache. The package cache hit ratio indicates how well the package cache is avoiding catalog accesses to packages and recompilations.
Metrics
A high package cache hit ratio (> 80%) indicates that the package cache is working well. In the case of static SQL statements, package caching allows the Database Manager to reduce the internal overhead by eliminating the need to access system catalogs when reloading a package. For dynamic SQL, the benefit of package caching is even greater since it a cache hit eliminates the need for recompilation. The package cache hit ratio metric is particularly important for transaction-processing applications since a typical workload involves repeatedly executing the same SQL statements.

Correction
Executing DDL statements can invalidate sections of SQL statements in the cache, causing the hit ratio to decrease dramatically. Before attempting to tune this parameter, you should check the DDL activity to see if that is causing a skew. No amount of tuning will improve the package cache performance if the DDL activity is causing package invalidations in the cache. If the DDL activity is minimal and package cache hit ratio is consistently small, consider increasing the package cache size (pckcachesz) in the database configuration. When increasing the value of this parameter, consider whether it might be more effective to allocate the extra memory being reserved to another purpose such as catalog cache or bufferpools.

Shared Workspace Hit Ratio
When sections are required by an application for executing dynamic or static SQL statements, they are placed in the shared workspace. The shared workspace exists at the application level and is shared among applications using the database. The hit ratio is a percentage indicating how well the shared SQL workspace is helping to avoid initialization of sections for SQL statements that are about to be executed. A high ratio indicates the shared workspace is successful in avoiding this action.
A shared workspace is shared by many applications. If applications have similar database access patterns, they can benefit greatly if they find required sections in the shared workspace. If an application finds a section in the shared workspace (e.g., a hit), that application avoids setup and initialization cost for that section. A high hit ratio is desirable for this metric. Typically, you should expect to see a high ratio (>80%) in transaction processing environments.

**Correction**
Shared workspace memory is allocated from the application control heap (app_ctl_heap_sz database configuration parameter) and increasing this may improve the hit ratio.

## Database Heap Utilization

There is one database heap per database, and the database manager uses it on behalf of all applications connected to the database. The database heap utilization is the percentage of database heap that is currently being used.

**Location**
IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Key Ratio Analysis Pane

**Metrics**
The database heap contains control block information for tables, indexes, table spaces, and bufferpools. It also contains space for event monitor buffers, the log buffer, and temporary memory used by utilities. The heap utilization can increase or decrease whenever any of the constituent elements change. If the utilization goes above 85% several times or stays above 85% for a sustained period, you may need to increase the maximum database heap size.

**Correction**
The dbheap database configuration parameter determines the maximum amount of heap memory that can be allocated. Examine the individual memory pools and how they are using the memory before increasing this parameter. An excessively large use of one of the memory pools may be the cause of this problem.

**Note:** On the main toolbar, click Memory and then Memory Pools to see the Memory Pools Details.

## Log Space Utilization

Log space utilization is the percentage of total available log space on the database that is currently being used.
Home View (DB2 LUW Performance Analyst)

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Key Ratio Analysis Pane

Metrics  Very high log space utilization (>75%) can indicate that the database might run out of log space soon. Usually, consistently high log space utilization has one of the following causes: Large transaction size. Applications are performing large numbers of updates on the database but are not committing the transactions frequently. The log space configured for the database is insufficient for the level of database activity. Very low log space utilization (< 5) % may indicate an excessively large log file and that you may be able to free some of the space occupied by log files on disk.

Correction  If the log utilization is mostly low but increases to near 100% for short periods, then you can increase the number of secondary log files (logsecond database configuration parameter). This allocates and deallocates additional log files as needed. If however, the log size is consistently high and changes frequently, you can increase the primary log size and/or the log file size (logfilsiz and logprimary database configuration parameters). Also, check the SQL activity on the SQL Activity tab of the Users Detail section to see if any applications are performing infrequent commits. If this is the case, evaluate whether such applications can be changed to have shorter transactions and hence less need for log space.

Lock List Utilization

Lock list utilization is the percentage of total database memory allocated for locks that is currently being used.
Metrics

There is only one lock list for each database and it contains the locks held by all applications connected to the database. Once the lock list is full, the database manager starts escalating row locks to table locks to free up space. This escalation may result in serious performance degradation because of reduced concurrency. Additionally, the number of deadlocks and transaction rollbacks may go up. If this metric reaches the 75% mark, you should consider bringing this percentage down with tuning.

Correction

Depending on the database’s activity level, you may be able to reduce the lock utilization by following these recommendations: Increase size of lock list: If there is not enough lock list space available, lock escalations will occur, increasing contention and reducing concurrency. Update the locklist database configuration parameter to increase this value. Tune applications to reduce locking: On the Locks tab of the Users detail section, identify the applications that are holding many locks and then consider the following steps for controlling the size of the lock list: Make the transactions shorter by increasing the COMMIT frequency. This ensures that locks are released frequently, thus freeing up lock space. Before you update many rows in a single table, lock the entire table (using the SQL LOCK TABLE statement). This prevents many row-level locks from being obtained (although this decreases concurrency). To control how locking is done for a specific table, use the LOCKSIZE parameter of the ALTER TABLE. To decrease the number of share locks held, use the Cursor Stability isolation level when possible. If the applications’ integrity requirements are not compromised, use Uncommitted Read instead of Cursor Stability to further decrease the amount of locking. Decrease percentage of lock list: If a small number of applications are consuming most of the lock space, decrease the percentage of lock list for each application. You can throttle back those applications by decreasing the maxlocks database configuration parameter. This reduces the amount of lock list memory available to each application thereby allowing for better distribution of lock list memory. NOTE: Decreasing the percentage of lock list should be a last resort, used only if you cannot decrease utilization with the other recommendations. It can cause a large number of lock escalations.

Shared Sort Memory Utilization

The amount of memory allocated for each sort may be some or all of the available sort heap size. Sort heap size is the amount of memory available for each sort as defined in the database configuration parameter sortheap. Shared sort memory utilization gives the percentage of the sort heap being used. It is possible for a single application to have concurrent sorts active. For example, in some cases a SELECT statement with a subquery can cause concurrent sorts.
Bottleneck Analysis Pane

When a DB2 database is active, applications accessing the database can either successfully access the database resources, or wait for resources to become available. Waiting applications can indicate normal database activity, or can indicate that a database bottleneck exists. A database administrator can use wait-based or bottleneck performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Performance Analyst Bottleneck analysis section helps a DBA isolate potential problem areas where there are waits, resource overloads or potential failures. If concurrency issues or heavy table scan activity is impacting database performance, you can use bottleneck analysis to isolate the root cause. Once one or more bottlenecks have been isolated as possible areas of interest, you can drill down and examine details on why the applications or resources are causing the problem. The Performance Analyst home page identifies the top system and application bottlenecks that may be currently a cause of lessened performance.

The following bottleneck indicators are used on the Performance Analyst Home page to succinctly communicate the general overall performance level of the monitored database:

- **Concurrency**
  - Apps Waiting on Locks
  - Avg. Lock Wait Time
  - Deadlocks Detected
  - Lock Escalations
- **Lock Timeouts**
  - I/O Activity
    - Log Pages I/O
    - Synchronous I/O
  - Object Bottlenecks
    - Accesses to Overflowed Records
    - Page Reorganizations
  - Sorts and Joins
    - Hash Join Overflows
    - Sort Overflows
  - Storage Bottlenecks
    - DMS Tablespaces Low on Space
    - Inaccessible Containers
    - Node with Smallest Log
    - Tablespaces in Abnormal State

### Apps Waiting on Locks

This metric gives the percentage of all currently connected applications that are waiting for locks.

- **Location**: IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Bottleneck Analysis Pane
- **Metrics**: If this number is high, you should investigate whether the applications are having concurrency problems.
- **Correction**: Compare this metric with the lock escalations metric to identify if the lock list memory is too small. Go to the Locks Waiting Details section of the Locks tab of the Users detail view and examine the lock activity at application level to identify the applications that are holding a large number of row locks and table-level locks. You may be able to tune the applications with high number of locks.

### Avg. Lock Wait Time

The average lock wait time metric gives the average amount of time applications waited for a lock in the database.
**Deadlocks Detected**

Deadlocks detected is the total number of deadlocks that have occurred since this instance of Performance Analyst started monitoring the database.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Bottleneck Analysis Pane

**Metrics** If a large number of deadlocks are detected, it can indicate that applications are experiencing lock contention problems. Deadlocks are usually caused by one of the following situations: Lock escalations on the database, Catalog tables locked for Repeatable Read, Applications are using inappropriate isolation levels at bind time, Applications are obtaining the same locks in a different order, Applications are locking tables explicitly where row level locks are sufficient.

**Correction** You may be able to modify the applications causing lock contentions for better concurrency. To identify the applications that may be causing contentions, go to the Lock Waits tab of the Users detail page and review the Application Details section.

**Lock Escalations**

The lock escalations metric indicates the number of times that locks have been escalated from row locks to table locks, since this instance of Performance Analyst started monitoring the database.
Location  IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Bottleneck Analysis Pane

Metrics  A lock is escalated when the total number of locks held by an application reaches the maximum amount it is allowed in the lock list memory. There are several possible causes of lock escalations: The database lock list size is too small for the concurrent workload. The maximum percentage of lock list memory allowed for each application is too small. One or more applications are obtaining an excessive number of locks. Monitor the lock escalations over a period of time to determine what levels are acceptable in your environment. If the escalations are excessive, or are accompanied by deadlocks or long lock waits, consider tuning the database.

Correction  Examine the locklist database configuration parameter together with the Lock List Utilization metric to see if the locklist size needs to be increased. If the lock list utilization is within acceptable range, try raising the maxlocks database configuration parameter to increase the percentage of lock list space available to each application. You should also examine the detailed lock usage for each application on the Locks tab of the Users detail page to see if applications are holding a high number of locks. In this case, tune your application for better concurrency.

Lock Timeouts

This metric identifies the number of times that a request to lock an object timed out without being granted.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Bottleneck Analysis Pane

Metrics  If the number of lock timeouts becomes excessive when compared to the acceptable range for your database, it can indicate that an application is holding locks for long durations. It can also indicate that the amount of time an application waits for a lock before timing out is too short. If you have too few lock timeouts and the average lock wait time is too high, it can indicate that the lock timeout configuration parameter is set to an excessively high value.

Correction  First you should examine the lock activity at the application level to identify any particular application that is causing excessive lock contentions. If so, you can tune the application to provide better concurrency. If lock timeouts are excessive, and average lock wait times are very short, you can increase the locktimeout database configuration parameter to make the applications wait longer before timing out.

Log Pages I/O

The log pages I/O statistic is the total number of pages that are read and written to the disk by the database logger.
**Synchronous I/O**

This metric presents the number of I/O operations that had to be performed synchronously by the database agents.

**Correction**

You can set the num_ioSERVER database configuration parameter to 1-2 more than the number of physical storage devices used by the database to ensure that parallel I/O is occurring. To minimize synchronous I/O, you may also need to layout your tablespace containers such that they are defined on different physical devices.

**Accesses to Overflowed Records**

This metric is the number of accesses (reads and writes) to overflowed rows in the database tables.

**Correction**

A row overflows if it is updated and no longer fits in the data page where it was originally written. This usually happens as a result of an update of a VARCHAR or an ALTER TABLE statement. Overflowed rows indicate that data fragmentation has occurred. If this number is high, you can try to improve performance by reorganizing the tables using the Space Analyst.

**Page Reorganizations**

The page reorganization statistic is the number of page reorganizations executed in the database.
Too many page reorganizations can result in less than optimal insert performance. You can use the Space Analyst to reorganize tables and eliminate fragmentation. You can also use the APPEND parameter for the ALTER TABLE statement to indicate that all inserts are appended at the end of a table and so avoid page reorganizations. In situations where updates to rows cause the row length to increase, the page may have enough space to accommodate the new row, but a page reorganization can be required to defragment that space. Or if the page does not have enough space for the new larger row, an overflow record is created that causes overflow accesses during reads. You can avoid both situations by using fixed length columns instead of varying length columns.

### Hash Join Overflows

Hash join is an option for the DB2 optimizer. A hash join compares the hash codes before comparing the predicates for tables involved in a join. This reduces the number of comparisons. The hash join overflows metric gives the percentage of all hash join operations that ran out of sort heap and may have required disk space for temporary storage since the current instance of Performance Analyst started monitoring the database.

### Sort Overflows

The sort overflows statistic is the total number of sorts that ran out of sort heap and that may have required disk space for temporary storage.
Metrics
When a sort overflows, additional overhead is incurred. The sort requires a merge phase and can potentially require more I/O if data needs to be written to disk.

Correction
Sort overflows can be reduced by increasing the sortheap database configuration parameter.

DMS Tablespaces Low on Space
The DMS Tablespaces Low on Space metric gives the number of DMS tablespaces in the database where more than 90% of the total available space is in use.

Metrics
This metric is an indicator that some of the tablespaces in your database may be running out of space. You should drill down to the Space metrics to identify the tablespaces that may be at the critical utilization level. In tablespaces where there are little or no inserts after the initial data is loaded, little or no free space may have been left on purpose. In such cases, it is normal to see a high utilization.

Correction
If this metric goes beyond the normal operational value for your database, consider creating additional space on the DMS tablespaces that are running out of space. You can do this by performing one or more of the following tasks: Clean up unused space by deleting the tables/indexes that are no longer required. Resize or extend the existing containers in the tablespaces. Add new containers to the tablespaces.

Inaccessible Containers
The inaccessible containers metric identifies the number of containers on all tablespaces that are currently inaccessible.
Inaccessible containers represent a serious problem on the database. The database is unable to access/write any data on an inaccessible container. Usually this is caused by either media errors or modifications to the container files/directories from outside DB2.

Correction: Drill down to the Space metrics to examine the inaccessible containers and the tablespaces on which they are contained. You may need to perform a redirected restore on the tablespace from a backup to correct this.

Node with Smallest Log

The node with smallest log metric is only returned for global snapshots and indicates the node with the least amount of available log space.

Correction: If the log utilization is mostly low but increases to near 100% for short periods, then you can increase the number of secondary log files (logsecond database configuration parameter). This allocates and deallocates additional log files as needed. If, however, the log size is consistently high and changes frequently, you can increase the primary log size and/or the log file size (logfilsiz and logprimary database configuration parameters). Also, check the SQL activity, under Users Drilldown > SQL activity to see if any applications are performing infrequent commits. If possible, such applications can be changed to have shorter transactions and less need for log space.

Tablespaces in Abnormal State

This metric is a count of the number of tablespaces in your database that are not in a 'Normal State'.
Home View (DB2 LUW Performance Analyst)

Location
IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Bottleneck Analysis Pane

IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics
Tablespaces in not normal state are not necessarily a cause for alarm. They may have been transitioned to that state intentionally by the DBA for maintenance related tasks. If this metric shows a value that is higher than you anticipated, you may need to drilldown to the Space metrics to see which tablespaces are not normal. A tablespace can be in one or more of the following states when it is not 'Normal': Quiesced: SHARE, UPDATE, EXCLUSIVE Pending: Load, delete, backup, roll forward, restore, disable, drop In progress: Roll forward, reorg, backup, TBS deletion, TBS creation Storage must be defined Restore in progress Offline and not accessible Storage may be defined Storage definition is in ‘final’ state Storage definition was changed prior to rollforward DMS rebalancer is active

Correction
If the number of 'Not Normal' tablespaces is higher than you expect, drill down to the space metrics to examine the abnormal tablespaces and take appropriate action.

SQL Analysis Pane

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured server down in terms of user response times.

Before you can identify problem SQL in your database, you need to understand the level of SQL activity that is occurring in the database. A high level overview of the type of SQL activity helps determine not only they types of statements that are being executed but also the type of internal activity they may be causing.

The following indicators are used on the Performance Analyst Home page to succinctly communicate the general overall performance level of the monitored database:

- Static SQL
- Dynamic SQL
- Units of Work
- Internal Rebinds
- Internal Rollbacks Due to Deadlocks

Static SQL

The static SQL metric is the number of static SQL statements that were executed on the database since the start of this instance of Performance Analyst.
Metrics
Together with dynamic and failed SQL statements, this metric represents the number of SQL statements executed on the database.

Dynamic SQL
This metric is the number of static SQL statements that were executed on the database since the start of this instance of Performance Analyst.

Metrics
Together with static and dynamic SQL statements, this metric represents the number of SQL statements executed on the database.

Failed SQL
The failed SQL metric is the number of failed SQL statements that were executed on the database since the start of this instance of Performance Analyst.

Metrics
Together with static and dynamic SQL statements, this metric represents the number of SQL statements executed on the database. This metric may also help you determine reasons for poor performance, since failed statements mean time wasted by the database manager. This results in lower throughput for the database.

Units of Work
This is the number of transactions executed on the database since the start of this instance of Performance Analyst.
Internal Rebounds

The internal rebounds metric is the number of automatic rebounds (or recompiles) that have been attempted on the database since the beginning of this instance of the Performance Analyst.

Internal Rollbacks Due to Deadlocks

The internal rollbacks due to deadlocks metric is the total number of forced rollbacks initiated by the database manager because of a deadlock for the current instance of Performance Analyst. A rollback is performed on the current unit of work in an application selected by the database manager to resolve the deadlock.

Storage Analysis Pane

While DBAs focus on memory settings and tuning SQL, they frequently forget how dangerous and insidious storage problems can be. This is not a good mindset because
storage headaches can play a major role in wrecking an otherwise well-running database.

Storage problems generally take one of two forms:

- The ‘hit-the-wall’ variety that can bring things to a complete standstill.
- The ‘performance vampire’ kind that slowly drains the performance of a database over time.

Storage problems have the capability to bring the curtain down on a database very quickly, as in the case of a transaction log running out of free space. But storage problems can also silently work behind the scenes to slowly, but surely rob a database of its performance. For example, a hub table in a busy database might be accessed very quickly when an application is first given life, but over time, if it develops a heavy forwarded row problem, it can cause things to run very differently.

The Storage Analysis section of the Performance Analyst Home page displays the total used and free space of all DMS tablespaces in the database. It also provides the total and available log space for the database.

The following ratios succinctly communicate the general overall performance levels of the datasource:

- **DMS Space**
- **Total SMS Space Used**
- **Log Space**
- **Last Backup**

## DMS Space

The total used and total free metrics show the space details for DMS tablespaces. Specifically, they show the amount of used and free space on the DMS tablespaces in the database.
Home View (DB2 LUW Performance Analyst)

Location IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Storage Analysis Pane IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DB2 LUW Performance Analyst) > Home > Storage Analysis Pane

Metrics Unlike SMS tablespaces, the total available space to the DMS tablespaces is defined at the time the database is defined. The DBA needs to explicitly increase the amount of space on DMS tables by adding/extending tablespace containers (using the ALTER TABLESPACE statement). If left unattended, a DMS tablespace can either remain underutilized or fill up completely. Keeping an eye on the DMS space is important because the once it fills up, the applications trying to write to the database will come to a halt suddenly.

Correction Go to the Space home page or drill-down to see the usage metrics for individual tablespaces and allocate/deallocate space to containers accordingly using ALTER TABLESPACE command.

Total SMS Space Used

This metric shows the total amount of SMS space used by the database.

Location IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Storage Analysis Pane IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DB2 LUW Performance Analyst) > Home > Storage Analysis Pane

Metrics The maximum size of SMS tablespaces is not set at the time the tablespaces are created. The maximum size that can be reached is the space available on the drives/volumes that the SMS tablespace containers are defined on. You need to periodically examine the available space of the drives/volumes (using OS metrics Space page) to make sure there is enough space available for your database requirements. Since the space is determined by the space available on the drives/volumes, remember that if other applications are reading and writing to the same devices (especially logs, traces, etc), DB2 may be periodically competing for space with these applications.

Correction Ideally, try and isolate the DB2 SMS drives/volumes from other applications. If the OS level metrics show that you are running out of space on a volume that is used by a tablespace’s containers, you can add more containers defined on volumes with more space, to the tablespace using the ALTER TABLESPACE command.

Log Space

The log space metrics show the amount of free and used log space on the database.
Location  IBM DB2 (W/U/L) Performance Analyst statistics  >  Home View (DBArtisan - DB2 LUW Performance Analyst)  >  Storage Analysis Pane

Metrics  Very high log space utilization (>75%) indicates that the database could run out of log space soon. Usually, consistently high log space utilization has one of the following causes: Large transaction size. Applications are performing a large number of updates on the database but are not committing the transactions frequently. The log space configured for the database is insufficient for the level of database activity. Very low log space utilization (< 5) % can indicate an excessively large log file. It's possible you can free some of the space occupied by log files on disk.

Correction  If the log utilization is mostly low but increases to near 100% for short periods, you can increase the number of secondary log files (logsecond database configuration parameter). This allocates and deallocates log files as needed. If however, the log size is consistently high, and changes frequently, you can increase the primary log size and/or the log file size (logfilsiz and logprimary database configuration parameters).

Also, check the SQL activity, under Users Drilldown>SQL activity to see if any applications are performing infrequent commits, and if possible such applications can be changed to have shorter transactions and hence less need for log space.

Last Backup

The last backup metric indicates when the database was last backed-up.

Location  IBM DB2 (W/U/L) Performance Analyst statistics  >  Home View (DBArtisan - DB2 LUW Performance Analyst)  >  Storage Analysis Pane

Workload Analysis Pane

When experiencing performance slowdowns, some of the first questions you should answer are:

- Who is currently connected to the database?
- What resources are they using?
- What are they currently executing?

The Workload Analysis section of the Performance Analyst Home page provides insight into the leading resource hogs of a server, as well as a count of total active and inactive processes. Drill-down’s are available so you can easily get detailed information into what each leading application is currently involved with.

Workload Analysis statistics include:

- Application Activity Analysis
- Applications Currently Executing
- Idle Applications
Application Activity Analysis

Ideally, database resource usage should be spread evenly across connected applications. In many cases, however, a couple of renegade applications can hog most of the resources and starve the other applications that are competing for the same resources. If you see a slowdown of the database, but cannot identify the root cause from ratio/bottleneck analysis, you need to examine any connected applications that are using more than their fair share of system resources (CPU, I/O, locklist, etc.).

Performance Analyst provides an easy way to identify the top users of the database resources and what percentage of total usage can be attributed to these applications.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Workload Analysis Pane

**Metrics**  
If any one application is using more than 50% of the total resource you should drill down into that application (Users drill-down) to isolate the problem.

Applications Currently Executing

The applications currently executing statistic gives the number of applications for which the database manager is currently executing requests.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Workload Analysis Pane

**Metrics**  
You can use this number to understand how many of the database manager agent tokens are being used by applications connected to this database

Idle Applications

The idle applications statistic the number of applications that are currently connected to the database for which the database manager is not executing any requests.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Home View (DBArtisan - DB2 LUW Performance Analyst) > Workload Analysis Pane

**Metrics**  
You can use this statistic to help you understand the level of activity within a database and the amount of system resources currently in use.
Memory View (DB2 LUW Performance Analyst)

The Memory category of DB2 Performance Analyst includes the following tabbed pages:

- Caches Tab
- Memory Pools Tab
- Lock Memory Tab

Home

The Home page of the Memory performance category view has statistics in the following categories:

- Key Ratio Analysis Pane
- Bottleneck Analysis Pane
- Memory Analysis Pane
- SQL Analysis Pane
- Workload Analysis Pane

Key Ratio Analysis Pane

Database performance analysts typically use one of two methods for examining the performance levels of a database - ratio-based or wait/bottleneck-based. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for busy DBAs to use for at-a-glance performance analysis. Many DBAs have large database farms to contend with and cannot spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving DBAs a few solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are certainly many opinions as to what rules to follow, there are some standards you should always adhere to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Most of the global ratios that a DBA will examine come from the DB2 Snapshot Monitor. The Snapshot Monitor returns various metrics for the instance and database since the start of monitoring. Some of the metrics are cumulative (i.e., counters) and others are instantaneous (i.e., gauges).

In the case of cumulative metrics, the values can grow quite large over the monitoring period and the ratios calculated on these metrics can hide the skews that may occur during the monitoring. However, if delta statistics are used (taking, for a specified
sampling period, the before and after counts of each statistic that make up a ratio), then an accurate and current portrayal of the database activity over the sampling period can be had.

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each DB2 databases’ individual personality with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following memory ratios are used on the Performance Analyst Key Ratio Analysis section to succinctly communicate the general overall memory performance levels of the monitored database:

- **Data Page Hit Ratio**
- **Private Workspace Hit Ratio**
- **Index Page Hit Ratio**

The following topics, available on this pane, duplicate statistics available on the Home View (DB2 LUW Performance Analyst) page:

- **Buffer Pool Hit Ratio**
- **Catalog Cache Hit Ratio**
- **Package Cache Hit Ratio**
- **Shared Workspace Hit Ratio**

**Data Page Hit Ratio**

This metric is the percentage of all data reads satisfied because the page was already available in a bufferpool.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Home > Key Ratio Analysis Pane

**Metrics** The index page hits are used in conjunction with data page hits to calculate the overall buffer pool hit ratio. Use this element, in conjunction with the index page hit ratio when tuning the overall buffer pool hit ratio.

**Private Workspace Hit Ratio**

Each application executing on the database has access to the private workspace of the agents working for it.

The private workspace hit ratio is a percentage indicating how well the private SQL workspace is helping to avoid initialization of sections for SQL statements that are about to be executed. A high ratio indicates it is successful in avoiding this action.
Correction

Shared workspace memory is allocated from the application heap (app_heap_sz database configuration parameter) and increasing this may improve the private workspace hit ratio.

Index Page Hit Ratio

The index page hit ratio is the percentage of all index reads that were satisfied because the page was already available in a bufferpool.

Metrics

The index page hits are used in conjunction with data page hits to calculate the overall buffer pool hit ratio. Use this element, in conjunction with the data page hit ratio when tuning the overall buffer pool hit ratio.

Bottleneck Analysis Pane

The Bottleneck Analysis section identifies the number of times when overflows or over-utilization may have occurred in areas of memory. An overflow occurs when the usage of a memory area goes beyond the allocated amount.

Overflows are serious bottlenecks and may cause unnecessary lock escalations, out of memory errors or performance degradations.

The following statistics are used on the Performance Analyst for DB2 Memory home page to succinctly communicate the general overall performance levels of the memory structures:

- Catalog Cache Overflows
- Hash Join Small Overflows
- Package Cache Overflows
- Private Workspace Overflows
- Shared Workspace Overflows

The following statistics, available on this pane, duplicate statistics available on the Bottleneck Analysis Pane of the Home View (DB2 LUW Performance Analyst) page.

- Hash Join Overflows
- Lock Escalations
- Sort Overflows
Catalog Cache Overflows

The catalog cache overflow statistic is the number of times the catalog cache overflowed the bounds of its allocated memory.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  
Catalog cache overflows can cause unnecessary lock escalations. This can result in loss of concurrency, or ‘out of memory’ errors from other heaps allocated to the database’s shared memory. Overflows of the catalog cache can also cause performance degradation. DB2 reclaims the catalog cache space by evicting table descriptor information for tables, views, or aliases and/or authorization information that is not currently being used by any transaction.

**Correction**  
Use this element with the catalog cache high watermark (Memory> Caches Drilldown) to determine whether the size of the catalog cache needs to be increased to avoid overflowing. If the number of overflows is large, the catalog cache may be too small for the workload. Enlarging the catalog cache can improve its performance. If the workload includes transactions that compile a large number of SQL statements referencing many tables, views, aliases, user-defined functions, or stored procedures in a single unit of work, then compiling fewer SQL statements in a single transaction can improve the performance of the catalog cache. Or, if the workload includes binding packages that contain many SQL statements referencing many tables, views, aliases, user-defined functions, or stored procedures, you can try splitting packages so that they include fewer SQL statements to improve performance.

Hash Join Small Overflows

The hash join small overflows statistic is the number of times that hash join data exceeded the available sort heap space by less than 10%.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  
If the value of hash join small overflows is greater than 10% of hash join overflows, then you should consider increasing the sort heap size. Values at the application level can be used to evaluate hash join performance for individual applications.

**Correction**  
Increase the sortheap database configuration parameter to reduce the number of overflows.

Package Cache Overflows

The package cache overflows metric is the number of times that the package cache overflowed the bounds of its allocated memory.
Memory View (DB2 LUW Performance Analyst)

**Location**  IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  Package cache overflows can cause unnecessary lock escalations. This can result in loss of concurrency, or ‘out of memory’ errors from other heaps allocated to the database’s shared memory. Overflows of the package cache can also cause performance degradation.

**Correction**  Use this element with the package cache high watermark (Memory > Caches Drilldown) to determine whether the size of the package cache needs to be increased to avoid overflowing.

**Private Workspace Overflows**

The private workspace overflows statistic is the number of times that private workspaces overflowed the bounds of their allocated memory.

**Location**  IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  Private workspace overflows can cause performance degradation as well as ‘out of memory’ errors from other heaps allocated to the agent’s private memory.

**Correction**  Use this element with the private workspace high watermark (Memory -> Caches Drilldown) to determine whether the size of the private workspace needs to be increased to avoid overflowing.

**Shared Workspace Overflows**

The shared workspace overflows metric is the number of times that shared workspaces overflowed the bounds of their allocated memory.

**Location**  IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  Overflows of shared workspaces can cause performance degradation. Overflows can also ‘out of memory’ errors from the other heaps allocated out of application’s shared memory.

**Correction**  Use this element with the shared workspace high watermark (Memory > Caches Drilldown) to determine whether the size of the shared workspaces need to be increased to avoid overflowing.

**Memory Analysis Pane**

This section helps you to track memory usage for database processes through Memory Analysis Heaps.

**Note:** The memory management for DB2 (and hence the metrics) varies between platforms. You only see the memory metrics at the database level for UNIX system. If
you are tracking the memory metrics for a Windows system, please refer to Instance -> Memory Pool Drilldown.

**Memory Analysis Heaps**

Under normal operating conditions you can track the memory usage for the following elements:

- Application Heap
- Database Heap
- Application Control
- Lock Manager Heap
- Backup/Restore/Utility Heap
- Statistics Heap
- Package Cache Heap
- Catalog Cache Heap
- DFM Heap
- Query Heap
- Database Monitor Heap
- Statement Heap
- FCMBP Heap
- Import Pool
- Other Memory
- Buffer Pool Heap

**Location**

IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Home > Memory Analysis Pane

**Metrics**

The various memory heap usages are useful when tuning the corresponding database configuration parameters.

**Correction**

To see greater details on the current utilizations, maximum available, and high watermarks, go to the Memory Pools tab of the Memory detail view. Based on these you can make decisions about whether you need to increase or decrease the maximum allocations for the heaps (mostly through database configuration parameters).

**SQL Analysis Pane**

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag an otherwise well-configured server down in terms of user response times.

Before you can identify problem SQL in your database, you need to understand the level of SQL activity that is occurring in the database. A high level overview of the type of SQL activity helps determine not only they types of statements that are being executed but also the type of internal activity they may be causing.

The following indicators are used on the Performance Analyst Memory page to succinctly communicate the general overall performance level of the monitored database. They duplicate statistics available on the SQL Analysis Pane of the Home View (DB2 LUW Performance Analyst) page:

- **Static SQL**
- **Dynamic SQL**
Memory View (DB2 LUW Performance Analyst)

- **Units of Work**
- **Internal Rebinds**
- **Internal Rollbacks Due to Deadlocks**

**Workload Analysis Pane**

When your phone starts ringing with complaints of performance slowdowns, one of the first things you should get a handle on is:

- Who is currently connected to the database?
- What resources are they using?
- What are they currently executing?

The Workload Analysis section of the Performance Analyst Memory page provides insight into the leading applications that caused memory overflows to disk or lock escalations. Drill down’s are available so you can easily get detailed information into what each leading application is currently involved with.

**Application Activity Analysis Pane**

Top memory issues are displayed in the following categories:

- Top Locks
- Top Lock Escalations
- Top Cache Overflows
- Top Sort Overflows
- Top Workspace Overflows

**Metrics**

The list of top memory hogs can help you quickly identify the applications that are causing memory usage problems. You can drill down into the Memory tab views to see how these applications are using memory compared to their peers and the overall memory being used by the database. This is a good place to start, if you think that the memory problems you are noticing on the database may be as a result of poorly written applications rather than database configuration or overall system memory availability.

**Caches Tab**

The Caches tab of the Memory Detail page offers detailed views of cache usage metrics and includes the following statistics:

- **Application Details**
- **Catalog Cache Usage Details**
The following statistics, available on this page, duplication statistics available on the Key Ratio Analysis Pane of the Home View (DB2 LUW Performance Analyst) page:

- **Catalog Cache Hit Ratio**
- **Package Cache Hit Ratio**
- **Shared Workspace Hit Ratio**

The following statistic, available on this page, duplication statistics available on the Caches Tab of the Memory View (DBArtisan - DB2 LUW Performance Analyst) page:

- **Private Workspace Hit Ratio**

### Application Details

The Application Details section shows the list of applications connected to the database and the various cache usage metrics for each application. It also shows the rolled up metrics at the database level in the same list. You can select the type of cache monitoring you intend to perform for the applications from the following:

- **Catalog Cache**: Shows the details of all catalog cache activity for connected applications
- **Package Cache**: Displays the details of all package cache activity for connected applications
- **Shared Workspace**: Gives the details of all shared workspace activity for connected applications
- **Private Workspace**: This shows the details all of private workspace activity for connected applications

### Catalog Cache Usage Details

This section shows detailed catalog cache usage metrics for the selected item. The metrics presented here include:
Memory View (DB2 LUW Performance Analyst)

- Catalog Cache Lookups: The number of times that the catalog cache was referenced to obtain table descriptor information or authorization information.
- Catalog Cache Inserts: The number of times that the system tried to insert table descriptor or authorization information into the catalog cache.
- Catalog Cache Overflows: The number of times that the catalog cache overflowed the bounds of its allocated memory.
- Catalog Cache High Watermark: The largest size reached by the catalog cache.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Caches Tab

**Metrics**  
These metrics are used for calculating the catalog cache hit ratio. They also give you an estimate of catalog access activity occurring in the database. You can use the catalog cache overflow metric with the catalog cache high watermark to determine if the catalog cache size is too small. If the catalog cache overflows frequently, you consider increasing the catalog cache size.

**Correction**  
If catalog cache overflows are large, the catalog cache may be too small for the workload. Enlarging the catalog cache may improve its performance. If the workload includes transactions that compile a large number of SQL statements referencing many tables, views, aliases, user-defined functions, or stored procedures in a single unit of work, then compiling fewer SQL statements in a single transaction may improve the performance of the catalog cache. Or if the workload includes binding packages that contain many SQL statements referencing many tables, views, aliases, user-defined functions, or stored procedures, you can try splitting packages. If they include fewer SQL statements, performance can improve. Monitor the catalog cache metrics for your normal workload. If you see frequent overflows, you can increase the value of catalogcache_sz database configuration parameter to the catalog cache high watermark/4096 (rounded up to whole integer).

**Package Cache Usage Details**

The Package Cache Usage Details section shows the detailed package cache usage metrics for the selected item. The metrics presented here include:

- Package Cache Lookups: The number of times that an application looked for a section or package in the package cache. At a database level, it indicates the overall number of references since the database was started, or monitor data was reset.
- Package Cache Inserts: The total number of times that a requested section was not available for use and had to be loaded into the package cache. This count includes any implicit prepares performed by the system.
- Package Cache Overflows: The number of times the package cache overflowed the bounds of its allocated memory.
- Package Cache High Watermark: The largest size reached by the package cache.
Metrics These metrics are used to calculate the package cache hit ratio. They also give you an estimate of package cache access activity occurring on the database. You can use the package cache overflow metric with the package cache high watermark to determine if the package cache size is too small. If the package cache overflows frequently, you may need to increase the package cache size.

Correction Monitor the package cache metrics for your normal workload. If you see frequent overflows, you can increase the value of the pckcachesz database configuration parameter to the package cache high watermark/4096 (rounded up to whole integer).

Private Workspace Usage Details

This section shows the detailed private workspace usage metrics for the selected item. The metrics presented here include:

- Private Workspace Lookups: Lookups of SQL sections by an application in its agents’ private workspace.
- Private Workspace Inserts: Inserts of SQL sections by an application into the private workspace.
- Private Workspace Overflows: The number of times that the private workspaces overflowed the bounds of its allocated memory.
- Private Workspace High Watermark: The largest size reached by the Private Workspace.

Correction You can reduce the chance of overflow by increasing APPLHEAPSZ.

Shared Workspace Usage Details

This section shows the detailed shared workspace usage metrics for the selected item. The metrics presented here include:

- Shared Workspace Lookups: Lookups of SQL sections by applications in shared workspaces.
- Shared Workspace Inserts: Number of inserts of SQL sections by applications into shared workspaces.
- Shared Workspace Overflows: The number of times that shared workspaces overflowed the bounds of their allocated memory.
- Shared Workspace High Watermark: The largest size reached by shared workspaces.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Caches Tab

**Metrics** These metrics are used to calculate the shared workspace hit ratio. They also give you an estimate of shared workspace access activity occurring on the database. When the shared workspace overflows, memory is temporarily borrowed from other entities in application shared memory. This can result in memory shortage errors from these entities or possibly performance degradation.

**Correction** You can reduce the chance of overflow by increasing APPL_CTL_HEAP_SZ.

### Memory Pools Tab

The Memory Pools tab offers the following detailed views:

- **Application Details**
- **Memory Pool Details**
- **Memory Pool Usage**
- **Memory Pool Utilization**

### Application Details

This section shows the list of applications connected to the database. You can select an application to show the breakdown of the memory pool usage by the application.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Memory Pools Tab

### Memory Pool Details

This section shows the memory pool usage details for the selected application (or database level) in the application details section. The metrics shown here include:

- **Pool ID**: This is the kind of memory pool. Each pool type is only shown once
- **Pool Current Size**: The current size of a memory pool.
- **Pool Max Size**: The internally configured size of a memory pool in DB2.
- **Pool High Watermark**: The largest size of a memory pool since its creation.
Memory Pool Usage

This section shows the memory pool usage details of the selected memory pool over time including the current size of the memory pool, its high watermark, and the maximum size of the memory pool.

Location

- IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Memory Pools Tab

Metrics

The nature of memory_pool data elements varies between platforms. On Windows systems, no memory usage is reported at the database level, while on UNIX systems, memory is reported at the database level. Instead of reporting this memory at the database level, the system monitor for Windows systems reports it in instance-level snapshots. This divergence in reporting is due to differences in the underlying memory architecture between Windows systems and UNIX systems.

Memory Pool Utilization

This section shows the percentage utilization of the selected memory pool.

Location

- IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Memory Pools Tab

Metrics

You can use this metric to see if a memory pool is nearly full. You can diagnose the problems with specific memory pools by monitoring their utilization over time.

Correction

If the value of the pool utilization is consistently close to or exceeds 100%, you may need to increase the configuration parameter associated with that pool.

Lock Memory Tab

The Lock Memory tab of the Memory Detail view shows the following statistics:

- **Lock List Utilization** (duplicates a statistics available on the Key Ratio Analysis Pane of the Home View (DB2 LUW Performance Analyst) page)

- **Lock Escalations**

Lock Escalations

This section shows the metrics for lock escalations in the database. The metrics shown here are:
Lock Escalations: The number of times that locks have been escalated from several row locks to a table lock.

Exclusive Lock Escalations: The number of times that locks have been escalated from several row locks to one exclusive table lock, or the number of times an exclusive lock on a row caused the table lock to become an exclusive lock.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Memory View (DBArtisan - DB2 LUW Performance Analyst) > Lock Memory Tab

Metrics  A lock is escalated when the total number of locks held by an application reaches the maximum amount of lock list space available to the application, or the lock list space consumed by all applications is approaching the total lock list space. The amount of lock list space available is determined by the maxlocks and locklist configuration parameters. When an application reaches the maximum number of locks allowed and there are no more locks to escalate, it will then use space in the lock list allocated for other applications. When the entire lock list is full, an error occurs. This data item includes a count of all lock escalations, including exclusive lock escalations. There are several possible causes for excessive lock escalations: The lock list size (locklist) may be too small for the number of concurrent applications The percent of the lock list usable by each application (maxlocks) may be too small One or more applications may be using an excessive number of locks.

Correction  To resolve these problems, you may be able to: Increase the locklist configuration parameter value. See the Administration Guide for a description of this configuration parameter. Increase the maxlocks configuration parameter value. See the Administration Guide for a description of this configuration parameter. Identify the applications with large numbers of locks (see locks_held_top), or those that are holding too much of the lock list, using the following formula: \[((\text{locks held} \times 36) / (\text{locklist} \times 4096)) \times 100\] and comparing the value to maxlocks. These applications can also cause lock escalations in other applications by using too large a portion of the lock list. These applications may need to resort to using table locks instead of row locks, although table locks may cause an increase in lock_waits and lock_wait_time.

I/O

In addition to a Home page, the I/O category of DB2 Performance Analyst includes the following tabbed pages are available on the I/O Detail view:

- Applications Tab
- Bufferpools Tab
- Logging Tab
- Tablespaces Tab

Home

The Home Page of the I/O performance category page displays the following vital DB2 I/O statistic categories:

- Key System Analysis Pane
The root cause of many database problems can be attributed to I/O-related operations. I/O monitoring is essentially a review of your physical database design. All physical storage characteristics and placements, table and index designs, and the speed with which all processes works are on display when I/O is monitored. Because a database’s main index of performance is measured by how fast I/O needs are satisfied, it is your responsibility to quickly determine if a reported database slowdown is I/O related.

The following statistics are used on the Performance Analyst for DB2 I/O Home Page to succinctly communicate the general overall performance levels of I/O:

- **Efficiency:**
  - Async Read Ratio
  - Async Write Ratio
  - Victim Page Cleaners %

- **Resource Utilization:**
  - Log Space Cleaners Triggered
  - Victim Page Cleaners Triggered
  - Threshold Cleaners Triggered

### Async Read Ratio

Async read ratio is the percentage of all index and data reads that performed asynchronously by the database manager prefetchers.
Prefetching refers to the technique whereby the Database Manager can read several pages on the physical reads device simultaneously into a bufferpool in anticipation of access to these pages. Since each physical read operation is costly, a 50% async read ratio is desirable. It shows that prefetchers are working well and read waits are minimal.

The num_ioserver database configuration parameter defines the number of prefetchers that are available for the database. To get an optimal async read ratio, you should set the num_ioserver database configuration parameter to 1-2 more than the number of physical storage devices used by the database to ensure that asynchronous I/O is occurring. This parameter should be changed judiciously. Having too many prefetchers invariably results in high system I/O because prefetchers can read many more pages than required into the bufferpools.

Async Write Ratio

Async write ratio is the percentage of all index and data writes that were performed asynchronously by the database manager bufferpool page cleaners.
Metrics
Page cleaners write changed pages from bufferpool to disk before the space in the bufferpool is needed by a database agent. If the page cleaners are not working well, the problem may manifest itself in two ways: The database agents need to synchronously free space in bufferpools resulting in poorer response time. If the system crashes, recovery time is greater because there will be a large number of pages that would not have been committed to disk at the time of the crash and they require processing for a large number of log records. An overall async write ratio of 50% is desirable for most transactional database systems. If your database is 'query only' (i.e., updates are rarely or never performed), it is fine to have an async write ratio of 0 to less than 50%. Even in 'query only' databases if the queries create temp tables on the database for intermediate results, a 30-40% async write ratio is desirable.

Correction
The async write ratio can be tuned using the num_iocleaners database configuration parameter, which specifies the number of asynchronous page cleaners for a database. Increasing the number of page cleaners generally results in a higher async write ratio. The following rules of thumb should be followed when tuning this parameter: For most transactional systems set this parameter to between one and the number of physical storage devices used by the database. For workloads that consists mainly of simple reads from the database, set this parameter to zero. When you define very large bufferpools on your database you may need to increase the num_iocleaners. Monitor the victim page cleaners % metric when tuning the num_iocleaners.

Victim Page Cleaners %
The victim page cleaners % metric is the percentage of times the page cleaners were invoked because synchronous write was needed during the victim buffer replacement in the database.
Memory View (DB2 LUW Performance Analyst)

**Location**  IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Home > Key System Analysis Pane

**Metrics**  Usually this metric should be maintained around the 50-60% level. If this ratio much lower than 50%, it can indicate that you have defined too many page cleaners. If the chngpgs_thresh database configuration parameter is set too low, the page cleaners may be writing out pages that will be dirtied later. Aggressive cleaning defeats one purpose of the bufferpool, that is to defer writing to the last possible moment. If this ratio is high, you may have too few page cleaners defined. This can increase recovery time after failures.

**Correction**  You may increase or decrease the chngpgs_thresh database configuration parameter to bring the victim page cleaner % to optimal range. Usually, for databases with heavy transaction workloads, chngpgs_thresh should be set to around 60%. For a database with only a few very large tables you can try and increase this parameter to a higher value to see if you get performance improvements.

**Log Space Cleaners Triggered**

The log space cleaners triggered metric is the number of times a page cleaner was triggered because log space usage reached a predefined threshold for the database.
**Location**

IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Home > Key System Analysis Pane

**Metrics**

The log space cleaners are triggered every time the space used by the DB2 log reaches the limit set in the softmax database configuration parameter. This parameter specifies the percentage of primary log size at which the cleaners are triggered. By default this parameter is set to 100. A low rate of log space cleaners getting triggered may indicate that logs are not being written to disk frequently enough and that you may need to process a large number of log records and redundant log records in the event of a crash recovery. High rates of log space cleaners getting triggered can indicate that your primary log is too small or that you have set the softmax too high. In either case, a very high rate of log cleaners being triggered may adversely impact database performance. It is important to keep in mind, however, that more page cleaner triggers and more frequent soft checkpoints increase the overhead associated with database logging. This can have an impact on the performance of the Database Manager. Also, more frequent soft checkpoints may not reduce the time required to restart a database, if you have: Very long transactions with few commit points. A very large bufferpool and the pages containing the committed transactions are not written back to disk very frequently. The use of asynchronous page cleaners can help avoid this situation. In both of these cases, the log control information kept in memory does not change frequently and there is no advantage in writing the log control information to disk, unless it has changed.

**Correction**

Examine this metric together with other page cleaner metrics and the async write ratio to determine if excessive numbers of log page cleaners are being triggered. If this is true, you need to either increase your primary log size or adjust the softmax parameter to a higher value.

**Note:** Decreasing the log page cleaner triggering rate can impact the overall crash recovery time so it needs to be done judiciously.

**Victim Page Cleaners Triggered**

The victim page cleaners triggered statistic is the number of times the page cleaners were invoked because synchronous write was necessary during the victim buffer replacement in the database.
If the chngpgs_thresh database configuration parameter is set too low, the page cleaners may be writing out pages that will be dirtied later. Aggressive cleaning defeats one purpose of the bufferpool, which is to defer writing to the last possible moment. If this ratio is high, it may indicate that you have too few page cleaners defined. Too few page cleaners increases recovery time after failures.

Correction
You may increase or decrease the chngpgs_thresh database configuration parameter to bring the victim page cleaner triggering rate to optimal range. For databases with heavy transaction workloads, chngpgs_thresh should be set to around 60%. For a database with only a few very large tables you can try and increase this parameter to a higher value to see performance improvements.

Threshold Cleaners Triggered

The threshold cleaners triggered metric is the number of times a page cleaner was invoked because a bufferpool had reached the dirty page threshold criterion for the database.

Correction
For databases with frequent update transactions, you can generally ensure that there are enough clean pages in the bufferpool by setting the chngpgs_thresh parameter value to be equal-to or less-than the default value. A percentage larger than the default can help performance if your database has a small number of very large tables.

Bottleneck Analysis Pane

High prefetch waits and file closures are good indicators of I/O waits at the database. Often, heavy I/O activity may not be due to non-optimal settings of the database configuration parameters. Rather, the underlying cause can be poor physical layout of a few tables/tablespaces or a few poorly written/suboptimal database applications. It is usually best to try and tune individual objects/applications before attempting to tune database configuration parameters. Database configuration changes can have a profound impact on every application and object that resides in the database and if there are only a couple of apps/objects dragging down the performance of the entire database, it may be best to first isolate and tune these.
I/O Bottleneck analysis provides information on applications and tablespaces that are performing the highest number of read and write operations on the database at a glance. It also shows the bufferpool I/O metrics that point to direct I/O waits.

The following statistics are used on the Performance Analyst for DB2 I/O home page to succinctly communicate the general overall performance levels of I/O:

- Hottest Tablespaces
- Hottest Apps
- Total Database Files Closed
- Total Time Spent Waiting for Prefetchers

### Hottest Tablespaces

This section displays the list of top three tablespaces with the highest number of physical reads and writes.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Home > Bottleneck Analysis Pane

**Metrics** Understanding the storage-level hot spots of a database is beneficial for two reasons. First, you can get a feel for overworked physical disks by viewing I/O statistics at the tablespace level. If a particular tablespace is under too much strain, you can attempt to relocate tablespace containers to other less-used devices. You can also try to create new tablespaces on different disks and move hot objects to them (assuming, of course, you have extra disks available). Second, if you have used standard DBA practices and placed indexes in their own tablespace, you can review the I/O statistics for the hottest tablespaces and see if the indexes are actually being used.

**Correction** Some areas to consider when reviewing the hottest tablespaces display are: A temp tablespace showing high volumes of physical I/O could indicate a problem with excessive sort overflows. Quickly review all physical I/O for each drive/file system at the OS level and get a feel for the overworked disks on your server. If you have underutilized disk drives (with their own controllers), then you should consider relocating some tablespaces/containers that exhibit high I/O characteristics to those drives. To minimize contention at the physical disk level, and to improve performance overall, it is generally recommended that a database have its tablespaces and log files physically separated onto different drives/file systems.

### Hottest Apps

This metric shows the top three applications connected to the database with the highest number of physical reads and writes.
A few applications with suboptimal queries/database accesses can drag down the performance of the entire database. The hottest apps section allows you to get a good feel for the applications that are causing the highest number of reads and writes on the database. It is also a good indicator of where you will reap the greatest benefit when tuning the application’s performance.

Drill down to the application I/O pages and see how the high I/O applications are behaving compared to other applications. Check the SQL Snapshot Metrics for the high read/write apps to see what queries these applications are running on the database and try to optimize these queries.

Both SMS tablespaces and DMS tablespace file containers are treated as files in the Database Manager’s interaction with the operating system, and file handles are required. There is a limit to the number of files that can be open concurrently by each database agent and a file is closed when the limit of open files for an agent is reached and the agent needs to open another file. This metric gives the number of times a database file was closed because the limit for concurrently open files was reached.

If you notice that files are being closed during the monitoring, first check the rate at which the files are being closed at the database level, from the I/O drill-down. If you see files being closed frequently, increase the maxfilop database configuration parameter. Note that the operating system on which the database is running also has a limit on the number of files that can be opened concurrently. Make sure that you do not increase the maxfilop parameter beyond the operating system limit.

This is the total time database applications spent waiting for prefetchers to finish loading.
Correction If you see a high number for this metric, it indicates there is a bottleneck in the prefetcher operations. Experiment with changing the number of I/O servers (num_ioserver) and the I/O server sizes.

SQL Analysis Pane

Most of database’s I/O performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag down an otherwise well-constructed server in terms of user response times. This section shows a snapshot of row level SQL operations that have been performed on the database since you started monitoring. This gives you an insight into the row level of read/write activity that is currently occurring within the database and comparing this to the prefetcher, and cleaner activity allows you to relate the two.

The following statistics are used on the Performance Analyst for DB2 I/O home page to succinctly communicate the general overall performance levels of I/O:

- Rows Deleted
- Rows Inserted
- Rows Selected
- Rows Updated
- Rows Read

Rows Deleted

The rows deleted metric is the total number of row deletions attempted on the database. It includes the internal row deletions that were caused by constraints or triggers.

Location IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Home > SQL Analysis Pane

Rows Inserted

The rows inserted metric is the total number of row insertions attempted on the database. This metric includes the internal row insertions that were caused by triggers.

Location IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Home > SQL Analysis Pane
Rows Selected

The rows selected statistic is the total number of rows selected at the database. This metric does not include a count of rows accesses for operations such as COUNT(*) or joins.

Rows Updated

The rows updated metric is the total number of row updates attempted on the database. This metric includes the internal row updates that were caused by triggers or constraints.

Rows Read

The rows read statistic is the number of rows read from the table. This count is not the number of rows that were returned to the calling application. Rather, it is the number of rows that had to be read in order to return the result set.

Non Buffered I/O Activity

Some database operations such as backups, loads, restores, LOB (large object I/O) bypass the bufferpools and read and write directly to storage. Sometimes, even if your database I/O configurations and all of the other activities are within the normal thresholds, the I/O performance may be poor because LOB reads/writes or load/backup/restore operations are causing or waiting on I/O contentions on your storage devices.

The non buffered I/O activity section allows you to quickly identify the level of direct I/O activity on the database. The level of direct I/O activity is succinctly presented using the following metrics:

- Direct Reads from the Database
Direct Reads from the Database

The direct reads from the database metric identifies the number of read operations that did not use a bufferpool. Direct reads are performed for the following database operations:

- Reading LONG VARCHAR columns
- Reading LOB (BLOB/CLOB/DBCLOB) columns
- Performing a backup

Location: IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Home > SQL Analysis Pane

Direct Writes to the Database

The direct writes to the database metric identifies the number of write operations that did not use a bufferpool. Direct writes are performed for the following database operations:

- Writing LONG VARCHAR columns
- Writing LOB (BLOB/CLOB/DBCLOB) columns
- Performing a load
- Performing a restore

Location: IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Home > SQL Analysis Pane

Direct I/O Averages

The following values show how well the direct I/O operations are performing:

- Avg. Sectors / Read: Average number of sectors read for each direct read operation
- Avg Sectors / Write: Average number of sectors written for each direct write operation
- Avg Read Time: Average read time per sector for direct reads
- Avg Write Time: Average write time per sector for direct writes
Location  IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Home > SQL Analysis Pane

Metrics  Understanding the level of direct I/O averages is important. A high level of activity with a slowdown in database performance can indicate that you need to have dedicated and/or high performance storage devices for your LOB objects or backup and load images. These metrics, when viewed with the device metrics at the OS level can also indicate I/O resource conflicts with other processes.

Correction  You can monitor these metrics for the LOB storage devices at the OS level to see if they are inordinately high for the database compared to the OS level. If so, there may be an I/O conflict with another process.

Workload Analysis Pane

When experiencing performance slowdowns, some of the first questions you should answer are:

- Who is currently connected to the database?
- What resources are they using?
- What are they currently executing?

The Workload Analysis section of the Performance Analyst I/O page provides insight into the leading resource hogs of a server, as well as a count of total active and inactive processes. Drill-down’s are available so you can easily get detailed information into what each leading application is currently involved with.

Workload Analysis statistics includes:

- Top I/O Apps

Top I/O Apps

The Top I/O Apps section gives a list of the apps with performing that are performing the highest number of most aggressive I/O activities. The list includes:

- Application with most bufferpool misses
- Application with highest direct reads and writes
- Application with highest sort overflows
- Application with highest direct read/write time

Application with highest bufferpool read write time
Correction Drill down to the application I/O level to see the details and compare the metrics with the application’s peers, and the database. In a lot of cases simple SQL rewrites, logic changes, and defining indexes based on access patterns can make a world of difference.

### Applications Tab

This section shows the list of applications connected to the database and the various I/O metrics for each application. It also shows the rolled up metrics at the database level in the same list. You can select the type of I/O monitoring you intend to perform for the applications from the following:

- **Direct I/O**: This shows the details of all direct I/O activity for the applications.
- **Buffered I/O**: This shows the details of all bufferpool I/O activity for the applications connected to the database.
- **Extended Storage**: This shows the level of extended storage usage by the applications.
- **Sorts & Joins**: This shows the details for the number of files closed for the various applications.
- **Block / Vectored I/O**: This shows the detailed of block and vectored I/O performed by the applications.

Correction Depending on the type of details you select, you can view the different types of I/O activity associated with the applications. This section is very useful in isolating the applications, and the I/O areas you need to tune by comparing the I/O performance for all the applications and also the overall I/O performance at the database level.

### Direct I/O

The Direct I/O Application or Tablespace Details view lets you the following statistics:

- **Direct Reads and Writes**
- **Direct Read and Write Requests**
- **#Direct Read and Writes Time**
Direct Reads and Writes

This section shows the rate at which direct read/write operations are occurring for the selected element. Direct I/O operations are those that do not use the bufferpools. Direct read and write operations are performed when:

- Reading/Writing LONG VARCHAR columns
- Reading/Writing LOB data
- Performing a backup operation
- Performing a restore operation
- Performing a load operation

Location [IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Applications Tab]

Metrics When using the performance analyst to track I/O, these elements help you distinguish the database I/O from the non-database I/O on storage devices.

Direct Read and Write Requests

This section shows the rate at which direct read/write operations requests are occurring for the selected element. Direct I/O operations are those that do not use the bufferpools. Direct read and write operations are performed when:

- Reading/Writing LONG VARCHAR columns
- Reading/Writing LOB data
- Performing a backup operation
- Performing a restore operation
- Performing a load operation
**Memory View (DB2 LUW Performance Analyst)**

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Applications Tab

**Metrics**  
Use these metrics together with the Direct R/W metrics and Direct R/W request metrics to determine if the rate at which the read/write occurring is similar to the rate at which they are being satisfied. If there is a large discrepancy between the Direct I/O request rates and Direct I/O rates, it may mean that there are I/O contentions on the device(s) where the direct I/O operations are being performed.

**Correction**  
If you suspect there are I/O contentions, you can investigate whether the contentions are being caused by the DB2 processes or other processes by examining the I/O metrics at the operating system level. Consider using dedicated devices for the direct I/O operations to reduce the contention levels.

**Direct Read and Writes Time**

This section shows the elapsed time to perform the direct I/O operations. Direct I/O operations are those that do not use the bufferpools. Direct read and write operations are performed when:

- Reading/Writing LONG VARCHAR columns
- Reading/Writing LOB data
- Performing a backup operation
- Performing a restore operation
- Performing a load operation

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Applications Tab

**Metrics**  
Use these metrics together with the Direct R/W metrics to determine average time it is taking to perform the read write operations. If the level of Direct I/O rates is low and the Direct RW times, it may mean that there are I/O contentions on the device(s) where the direct I/O operations are being performed.

**Correction**  
If you suspect there are I/O contentions, you can investigate whether the contentions are being caused by the DB2 processes or other processes by examining the I/O metrics at the operating system level. Consider using dedicated devices for the direct I/O operations to reduce the contention levels. If the contention levels are low, you may also benefit from using faster storage devices for direct I/O.

**Buffered I/O**

The Buffered I/O Application Details view lets you see the following statistics:

- Hit Ratios
- Write/Read Ratios
Hit Ratios

The DB2 database server reads and updates all data from a bufferpool because memory access is much faster than disk access. Data is copied from disk to a bufferpool as needed by the applications using the database. When the server needs to read/write data and the data is already in the bufferpool, no disk access is required. However, if the data is not in the bufferpool, it needs to be read from the disk, which is significantly slower process.

The buffer pool hit ratio indicates the percentage of time that the database server did not need to load a page to service the request for a page. The calculation takes into account all the index and data pages that were requested.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Applications Tab

Metrics  Avoiding disk I/O is the main issue when trying to improve performance tuning. A high buffer pool hit ratio is desirable because it indicates a lower frequency of synchronous disk I/O. A database where data is accessed uniformly from very large tables will have a poor hit ratio. There is little you can do to improve the performance in such cases.

Correction  The buffer pool hit ratio on the database Home page is the overall hit ratio of the database. First, drill down to the bufferpool level and check the individual buffer pool hit ratios to identify the elements that may require tuning. Increasing the bufferpool size generally improves the buffer pool hit ratio. You can use one of the following methods to increase the bufferpool size depending on the layout of the data: If the tablespaces using the bufferpool have tables and indexes on them, increase the bufferpool size incrementally until the index page hit ratio stops increasing for that bufferpool. You will not usually get any benefit increasing the bufferpool size after you reach that point. If the tablespaces associated with the bufferpool have only indexes on them, increase the bufferpool size until the index page hit ratio stops increasing. If the tablespaces associated with the bufferpool have only data on them, increase the bufferpool size until the data page hit ratio stops increasing. One general design guideline is to try and use different tablespaces for indexes and tables and associate different bufferpools with them. This generally improves performance and makes bufferpool tuning much easier.

Write/Read Ratios

This section shows the overall level of read / write activity being performed on the selected element.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Applications Tab

Extended Storage

The Extended Storage Application or Transaction Details view lets you see the following statistics:

- Index I/O on Extended Storage
- Data I/O on Extended Storage
Index I/O on Extended Storage

This section shows the Index Pages copied to/from extended storage for the selected element. On 32-bit platforms, virtual addressable memory is usually limited to between 2 and 4 GB. If your 32-bit machine has more real addressable memory than the maximum amount, you can configure any additional real addressable memory beyond virtual addressable memory as an extended storage cache. Any of the defined bufferpools can use an extended storage cache to improve performance. You define the extended storage cache as a number of memory segments.

The bufferpools perform first-level caching, and any extended storage cache is used by the bufferpools as secondary-level caching. Ideally, the bufferpools hold the data that is most frequently accessed, while the extended storage cache hold data that is accessed less frequently.

Pages are copied from the bufferpool to extended storage, when they are selected as victim pages. This copying is required to make space for new pages in the bufferpool.

Required index pages are copied from extended storage to the bufferpool, if they are not in the bufferpool, but are in extended storage. This copying may incur the cost of connecting to the shared memory segment, but saves the cost of a disk read.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Applications Tab

Metrics  Because an extended storage cache is an extension to a bufferpool, it must always be associated with one or more specific bufferpools. Therefore, only the bufferpools that are declared to take advantage of advantage of the extended storage use it. The CREATE and ALTER BUFFERPOOL statements have the attributes NOT EXTENDED STORAGE and EXTENDED STORAGE that control cache usage. By default neither IBMDEFAULTBP nor any newly created bufferpool will use extended storage. Use these metrics together with the Data I/O on Extended Storage metrics to determine the level of I/O being performed on extended storage. If there is significant activity on this section, you may improve performance by increasing the size of extended storage.

Correction  The amount of extended storage for a database is determined by the following two database configuration parameters: num_estore_segs defines the number of extended storage memory segments. The default for this configuration parameter is zero, which specifies that no extended storage cache exists. estore_seg_sz defines the size of each extended memory segment. This size is determined by the platform on which the extended storage cache is used.

Data I/O on Extended Storage

This section shows the DataPages copied to/from extended storage for the selected element.

On 32-bit platforms, virtual addressable memory is usually limited to between 2 and 4 GB. If your 32-bit machine has more real addressable memory than the maximum amount, you can configure any additional real addressable memory beyond virtual addressable memory as an extended storage cache. Any of the defined bufferpools can
use an extended storage cache to improve performance. You define the extended storage cache as a number of memory segments.

The bufferpools perform the first-level caching, and any extended storage cache is used by the bufferpools as secondary-level caching. Ideally, the bufferpools hold the data that is most frequently accessed, while the extended storage cache hold data that is accessed less frequently.

Pages are copied from the bufferpool to extended storage, when they are selected as victim pages. This copying is required to make space for new pages in the bufferpool. Required pages are copied from extended storage to the buffer pool, if they are not in the bufferpool, but are in extended storage. This copying may incur the cost of connecting to the shared memory segment, but saves the cost of a disk read.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Applications Tab

**Metrics** Because an extended storage cache is an extension to a bufferpool, it must always be associated with one or more specific bufferpools. Therefore, only the bufferpools that are declared to take advantage of the extended storage use it. The CREATE and ALTER BUFFERPOOL statements have the attributes NOT EXTENDED STORAGE and EXTENDED STORAGE that control cache usage. By default neither IBMDEFAULTBP nor any newly created bufferpool will use extended storage. Use these metrics together with the Index I/O on Extended Storage metrics to determine the level of I/O being performed on extended storage. If there is significant activity on this section, you can improve performance by increasing the size of extended storage.

**Bufferpools Tab**

This section shows the list of bufferpools on the database and the various I/O metrics for each bufferpool. It also shows the rolled up metrics at the database level in the same list. You can select the type of monitoring you intend to perform for the bufferpools from the following:

- **Direct I/O**: This shows the details of all direct I/O activity for the various bufferpools
- **Buffered I/O**: This shows the details of all bufferpool I/O activity for the various bufferpools in the database
- **Extended Storage**: This shows the level of extended storage usage by the various bufferpools that use extended storage
- **Total Database Files Closed**: This shows the details for the number of files closed for the various bufferpools in the database
- **Block/Vectored I/O**: This shows the detailed of block and vectored I/O performed by the various bufferpools.

**Correction**

Depending on the type of details you select, you can view the different types of I/O activity associated with the bufferpools. This section is very useful in isolating the
bufferpools, and the I/O areas you need to tune by comparing the I/O performance for all the bufferpools and also the overall I/O performance at the database level.

**Block/Vectored I/O**

The Block/Vectored I/O section of the Bufferpool Details view displays the following statistics:

- Vectored I/O
- Block I/O

**Vectored I/O**

The Vectored I/O section gives the metrics for vectored I/O requests and reads.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Bufferpools Tab

**Metrics** Use this element to determine how often vectored I/O is being done. The number of vectored I/O requests is monitored only during sequential prefetching.

**Block I/O**

The Block I/O section gives the metrics for block I/O requests and reads. If block-based bufferpool is enabled, this section reports how often block I/O is being done. The number of block I/O requests is monitored only during sequential prefetching when using block-based bufferpools.
Memory View (DB2 LUW Performance Analyst)

**Location**
IBM DB2 (W/U/L) Performance Analyst statistics > I/O > Bufferpools Tab

**Metrics**
If block-based bufferpool is enabled and the block I/O activity is very low, or close to the values in the vectored I/O section, consider changing the block size. This state can be an indication of the following: The extent size of one or more tablespaces bound to the bufferpool is smaller than the block size specified for the bufferpool. Some pages requested in the prefetch request are already present in the page area of the bufferpool. The prefetcher allows some wasted pages in each bufferpool block, but if too many pages are wasted, then the prefetcher will decide to perform vectored I/O into the page area of the bufferpool. To take full advantage of the sequential prefetch performance improvements that block-based bufferpools provide, it is essential to choose an appropriate value for the block size. This can, however, be difficult because multiple tablespaces with different extent sizes can be bound to the same block-based bufferpool. For optimal performance, it is recommended that you bind tablespaces with the same extent size to a block-based bufferpool with a block size equal to the extent size. Good performance can be achieved when the extent size of the tablespaces are greater than the block size, but not when the extent size is smaller than the block size. For example, if extent size is 2 and block size is 8, vectored I/O would be used instead of block I/O (block I/O would have wasted 6 pages). A reduction of the block size to 2 would solve this problem.

**Correction**
You can alter the block size for a buffer pool using the ALTER BUFFERPOOL ddl statement.

**Logging Tab**
The Logging tab of the I/O Detail view displays Logging I/O statistics. This section shows the level of read/write activity being performed by the logger. The information presented here is:

- **Log Reads**: The number of log pages read from the disk by the logger per second.
- **Log Writes**: The number of log pages written to the disk by the logger.

**Metrics**
You can use this page with the operating system level I/O metrics, to quantify the amount of I/O on a device that is attributable to database activity.

**Tablespaces Tab**
The **Tablespace** tab of the I/O detail view shows the list of tablespaces in the database and the I/O metrics for each tablespace. It also shows the rolled-up metrics at the database level in the same list. You can select the type of monitoring you intend to perform for the tablespaces from the following:

- **Direct I/O**: Shows the details of all direct I/O activity for the various tablespaces
- **Buffered I/O**: Shows the details of all bufferpool I/O activity for the various tablespaces in the database
- **Extended Storage**: Shows the level of extended storage usage by the tablespaces that use extended storage
- **Total Database Files Closed**: Shows details for the number of files closed for various tablespaces in the database

**Correction**

Depending on the type of details you select, you can view the different types of I/O activity associated with the tablespaces. This section is very useful in isolating the tablespaces, and the I/O areas you need to tune by comparing the I/O performance for all the tablespaces and also the overall I/O performance at the database level.

**Buffered I/O**

The following statistics are available on the Buffered I/O section of the Tablespace Details of the I/O view:

- **Hit Ratios**
- **Async I/O**
- **Write/Read Ratios**

**Async I/O**

Async read ratio is the percentage of all index and data reads that were performed asynchronously by the database manager prefetchers. Async write ratio is the percentage of all index and data writes that were performed asynchronously by the database manager bufferpool page cleaners.
Prefetching refers to the technique whereby the Database Manager can read several pages on the physical reads device simultaneously into a bufferpool in anticipation of an access to these pages. Since each physical read operation is costly, a 50% async read ratio is desirable since it shows that the prefetchers are working well and read waits are being minimized. Page cleaners write changed pages from bufferpool to disk before the space in the bufferpool is needed by a database agent. If the page cleaners are not working well, the problem may manifest itself in two ways: The database agents will need to synchronously free up space in bufferpools resulting in poorer response time. If the system crashes, the recovery time of the system will be greater because there will be a large number of pages that would not have been committed to disk at time of crash and will require processing of a large number of log records. An overall async write ratio of 50% is desirable for most transactional database systems. If your database is ‘query only’ (i.e., updates are rarely or never performed), it is okay to have an async write ratio of 0 to less than 50%. Even in ‘query only’ databases if the queries create temp tables on the database for intermediate results, a 30-40% async write ratio is desirable.

Correction

num_ioserver database configuration parameter defines the number of prefetchers that are available for the database. To get an optimal async read ratio, you should set the num_ioserver database configuration parameter to 1-2 more than the number of physical storage devices used by the database to ensure that asynchronous I/O is occurring. This parameter should be changed judiciously since having too many prefetchers invariably results in high system I/O because prefetchers can read many more pages than required into the bufferpools. Async write ratio can be tuned using the num_iocleaners database configuration parameter. This parameter specifies the number of asynchronous page cleaners for a database. Increasing the number of page cleaners generally results in a higher async write ratio. The following rules of thumb can be followed when tuning this parameter: For most transactional systems set this parameter to between 1 and the number of physical storage devices used by the database. For workloads that consists of mainly simple reads from the database, set this parameter to 0. When you define very large bufferpools on your database you may need to increase the num_iocleaners. Monitor the victim page cleaners% metric when tuning the num_iocleaners.
Space View (DB2 LUW Performance Analyst)

While DBAs focus on memory settings and tuning SQL, they often forget just how dangerous and insidious storage problems can be. This is not a good mindset because storage headaches can play a major role in wrecking an otherwise well-running database.

Storage problems generally take one of two forms:

- The 'hit-the-wall' variety that can bring things to a complete standstill
- The 'performance vampire' kind that slowly drains the performance of a database over time

Storage problems can quickly lead to performance problems, such as when a transaction log runs out of free space. But storage problems can also silently work behind the scenes to slowly but surely rob a database of its performance.

In addition to a Home page, the Space category of DB2 Performance Analyst includes the following tabbed pages:

- Usage tab
- Logging tab
- Bufferpools tab
- Objects tab
- Quiesce tab
- Rebalance tab
- Reorganization tab
- Rollforward tab

Home

The Home page of the Space performance category view displays statistics in the following categories:

- Tablespace Analysis Pane
- Bottleneck Analysis Pane
- SQL Analysis Pane
- Storage Analysis Pane
- Log Analysis Pane
Tablespace Analysis Pane

The Tablespace Analysis section includes a list of all of the tablespaces in the database. The following information is presented for each tablespace:

- **Tablespace Name**: The name of the tablespace
- **Type**: system managed (SMS) or database managed (DMS) tablespace
- **State**: This element describes the current state of the tablespace
- **Used Space**: The space currently in use on tablespace
- **Free Space**: The space currently free on the tablespace. (This is not applicable to SMS tablespaces)
- **Content Type**: The type of data that can be stored on the tablespace. It can be one of the following:
  - **Any**: (any type of data)
  - **Long**: (LOB/ Structured type / Index data)
  - **System Temporary**: (work area used by database manager to perform operations like sorts and joins)
  - **User Temporary**: (Stores declared global temporary tables)
- **Page Size**: Size of pages used by the tablespace
- **Extent Size**: Number of pages that will be written to a container before writing to the next container on the tablespace
- **Prefetch Size**: Number of pages that will be read from the tablespace by the prefetchers in a single prefetch
- **Total Space**: Total space (Used + Free) used by the tablespace on the storage device(s). This will be the same as used space for SMS tables
- **High Watermark**: Highest amount of used space for the tablespace (This is not applicable to SMS tablespaces)

Other statistics appearing in this section include:
The total tablespaces statistic is the total number of tablespaces in the database.

The SMS tablespaces statistic is the number of system managed (SMS) tablespaces in the database.

The DMS tablespaces statistic is the number of database managed (DMS) tablespaces in the database.

### Bottleneck Analysis Pane

Space shortfalls or inaccessible tablespaces can quickly bring a database to a halt. The space bottleneck analysis section provides an at a glance look at the items that may require your attention. You can drilldown to the details pages to see further details of the various metrics.

The metrics presented here are:

- **DMS Tablespaces at Utilization >80%**
- **Inaccessible Tablespaces**

The following statistics, available on this pane, are duplicates of statistics found on the Bottleneck Analysis Pane of the Home View (DB2 LUW Performance Analyst) page:

- **Inaccessible Containers**
- **Tablespaces in Abnormal State**

### DMS Tablespaces at Utilization >80%

The DMS tablespaces at utilization greater than 80% metric gives the number of DMS tablespaces in the database where the used space on the tablespace is more than 80% of the total available space.
**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  
This metric is an indicator that some of the tablespaces in your database may be running out of space. You should drill down to the Space metrics to identify the tablespaces that may be at the critical utilization level. In tablespaces where there are little or no inserts after the initial data is loaded, little or no free space may have been left on purpose. In such cases, it is normal to see a high utilization.

**Correction**  
If this metric goes beyond the normal operational value for your database, consider creating additional space on the DMS tablespaces that are running out of space. You can do this by performing one or more of the following tasks: Clean up unused space by deleting the tables/indexes that are no longer required. Resize or extend the existing containers in the tablespaces. Add new containers to the tablespaces.

**Inaccessible Tablespaces**

The inaccessible tablespaces statistic is the number of tablespaces that are offline.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  
Sometimes a problem (such as inaccessible containers) will cause a tablespace to go offline. Even when the problem is corrected, such tablespaces are not accessible by any application and need to be brought online explicitly.

**Correction**  
From Tablespace Analysis section, identify the tablespaces whose state is set to Offline. Drill down to space details to make sure all of the containers for these tablespaces are accessible. If they are not, first fix the problem with the containers Disconnect all applications from the database (you can use DBArtisan DB Monitor). Reconnect to the database. Use the ALTER TABLESPACE .. SWITCH ONLINE command to bring the tablespace back online. If the tablespace can be brought up successfully after issuing the command, or if the tablespace was not in the OFFLINE state to begin with, DB2 returns an SQLCODE of 0. If the tablespace cannot be brought up successfully because there are still problems with one or more of the containers, DB2 returns an SQLCODE of --293. You can force the database to restart by using the RESTART ... DROP PENDING TABLESPACE, but have to drop any faulty table spaces afterward.

**SQL Analysis Pane**

The metrics presented here are:

- DDL Statements Executed
- Insert/Updates/Deletes Statements Executed
- Select Statements Executed
- Total SQL Executed
DDL Statements Executed

This metric indicates the number of SQL Data Definition Language (DDL) statements that have been executed.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Home > SQL Analysis Pane

**Metrics** You can use this element to determine the level of database activity at the application or database level. DDL statements are expensive to run because of their impact on the system catalog tables. As a result, if the value of this element is high, you should determine the cause, and possibly restrict this activity from being performed. DDL statements can also impact: The catalog cache, by invalidating table descriptor information and authorization information that are stored there and causing additional system overhead to retrieve the information from the system catalogs. The package cache, by invalidating sections that are stored there and causing additional system overhead due to section recompilation.

Insert/Updates/Deletes Statements Executed

This is the number of SQL UPDATE, INSERT, and DELETE statements that were executed.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Home > SQL Analysis Pane

**Metrics** You can use this element to determine the level of database activity at the application or database level. This information can be useful for analyzing application activity and throughput.

Select Statements Executed

This statistic is the number of SQL SELECT statements that were executed.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Home > SQL Analysis Pane

**Metrics** You can use this element to determine the level of database activity at the application or database level. This information can be useful for analyzing application activity and throughput.

Total SQL Executed

You can use this element to calculate the total number of SQL statements at the database level.
Storage Analysis Pane

While DBAs focus on memory settings and tuning SQL, they frequently forget how dangerous and insidious storage problems can be. This is not a good mindset because storage headaches can play a major role in wrecking an otherwise well-running database. Storage problems generally take one of two forms:

- The ‘hit-the-wall’ variety that can bring things to a complete standstill.
- The ‘performance vampire’ kind that slowly drains the performance of a database over time.

Storage problems have the capability to bring the curtain down on a database very quickly, as in the case of a transaction log running out of free space. But storage problems can also silently work behind the scenes to slowly, but surely rob a database of its performance. For example, a hub table in a busy database might be accessed very quickly when an application is first given life, but over time, if it develops a heavy forwarded row problem, it can cause things to run very differently.

The Storage Analysis section of the Performance Analyst Home page displays the total used and free space of all DMS tablespaces in the database. It also provides the total and available log space for the database.

The following ratios succinctly communicate the general overall performance levels of the datasource:

- Log Space
- Last Backup

The following statistics, available on this pane, duplicate statistics available on the Storage Analysis Pane of the Home page:

- DMS Space
- Total SMS Space Used

Log Analysis Pane

The Log Analysis section gives you at-a-glance information about all your log configuration parameters and the high watermarks for the log space usage. You can use this information to quickly determine the logging mechanism in place for your database.
and if the high watermarks are getting too close to the maximum allocations for the log space.

The metrics presented here are:

- **Log Configuration**
- **High Watermarks**

### Log Configuration

The log configuration metric gives a list of space related log configuration parameters for your database. The values of these parameters determine how the logger uses storage space on the database:

- **Block on Log Disk Full (blk_log_dsk_ful):**
  This configuration parameter can be set to prevent disk full errors from being generated when DB2 cannot create a new log file in the active log path. Instead, DB2 will attempt to create the log file every five minutes until it succeeds. After each attempt, DB2 will write a message to the administration notification log. The only way to confirm that your application is hanging because of a log disk full condition is to monitor the administration notification log. Until the log file is successfully created, any user application that attempts to update table data is not able to commit transactions. Read-only queries may not be directly affected; however, if a query needs to access data that is locked by an update request or a data page that is fixed in the bufferpool by the updating application, read-only queries also appear to hang.

Setting `blk_log_dsk_ful` to YES causes applications to hang when DB2 encounters a log disk full error. You are then able to resolve the error and the transaction can continue. A disk full situation can be resolved by moving old log files to another file system, or by increasing the size of the file system so that hanging applications can complete.

If `blk_log_dsk_ful` is set to NO, a transaction that receives a log disk full error fails and is rolled back. In some cases, the database comes down if a transaction causes a log disk full error.

- **Log File Size (logfilsiz):**
  Specifies the size of each configured log, in number of 4-KB pages.

There is a 256-GB logical limit on the total active log space that you can configure. This limit is the result of the upper limit on `logfilsiz`, which is 262144, and the upper limit on `(logprimary + logsecond)`, which is 256.

The size of the log file has a direct bearing on performance. There is a performance cost for switching from one log to another. So, from a pure performance perspective, the larger the log file, size the better. This parameter also indicates the log file size for archiving. In this case, a larger log file is size it not necessarily better, since a larger log file size may increase the chance of failure or cause a delay in log shipping scenarios. When considering active log space, it may be better to have a larger number of smaller log files. For example, if there are two very large log files and a transaction starts close to the end of one log file, only half of the log space remains available.
Every time a database is deactivated (all connections to the database are terminated), the log file that is currently being written is truncated. So, if a database is frequently being deactivated, it is better not to choose a large log file size because DB2 will create a large file only to have it truncated. You can use the ACTIVATE DATABASE command to avoid this cost, and having the bufferpool primed will also help with performance.

Assuming that you have an application that keeps the database open to minimize processing time when opening the database, the log file size should be determined by the amount of time it takes to make offline archived log copies.

Minimizing log file loss is also an important consideration when setting the log size. Archiving takes an entire log. If you use a single large log, you increase the time between archiving. If the medium containing the log fails, some transaction information will probably be lost. Decreasing the log size increases the frequency of archiving but can reduce the amount of information loss in case of a media failure since the smaller logs before the one lost can be used.

- **Log Retain (logretain):** if logretain is set to RECOVERY, archived logs are kept in the database log path directory and the database is considered to be recoverable, meaning that rollforward recovery is enabled.

**Note:** The default value for the logretain database configuration parameter does not support rollforward recovery and must be changed if you are going to use it.

- **User Exit (userexit):** causes the database manager to call a user exit program for archiving and retrieving logs. The log files are archived in a location that is different from the active log path. If userexit is set to ON, rollforward recovery is enabled.

**Note:** The userexit database configuration parameter must be enabled to set logsecond parameter to 1

- **Primary Logs (logprimary):** specifies the number of primary logs of size logfilsz that will be created.

A primary log, whether empty or full, requires the same amount of disk space. Thus, if you configure more logs than you need, you use disk space unnecessarily. If you configure too few logs, you can encounter a log-full condition. As you select the number of logs to configure, you must consider the size to make each log and whether your application can handle a log-full condition. The total log file size limit on active log space is 256 GB.

If you are enabling an existing database for rollforward recovery, change the number of primary logs to the sum of the number of primary and secondary logs, plus 1. Additional information is logged for LONG VARCHAR and LOB fields in a database enabled for rollforward recovery.

- **Secondary Logs (logsecond):** specifies the number of secondary log files that are created and used for recovery, if needed.

If the primary log files become full, secondary log files (of size logfilsiz) are allocated, one at a time as needed, up to the maximum specified by this parameter. If this
parameter is set to -1, the database is configured with infinite active log space. There is no limit on the size or number of in-flight transactions running on the database.

**Note:** If this parameter is set to -1, crash recovery time may be increased since DB2 may need to retrieve archived log files.

Location [IBM DB2 (W/U/L) Performance Analyst statistics](#) > Space View (DBArtisan - DB2 LUW Performance Analyst) > Home > Log Analysis Pane

## High Watermarks

The high watermarks statistic shows the maximum total and secondary log space used by the database.

**Location** [IBM DB2 (W/U/L) Performance Analyst statistics](#) > Space View (DBArtisan - DB2 LUW Performance Analyst) > Home > Log Analysis Pane

**Metrics** The total log space used high watermark in conjunction with the total log space allocated, helps you determine if applications have come close to using the total log space available to your database. The total secondary log space used high watermark in conjunction with total log space used high watermark helps you determine your current dependency on secondary logs.

**Correction** High values of either high watermarks can indicate that you either need to increase the log space on the database or that the applications using the database need to perform more frequent COMMITS. You can increase the overall log space available by adjusting one or more of the following database configuration parameters: `logfilsiz`, `logprimary`, `logsecond`, and `logretain`.

## Usage tab

The Space Detail Usage tab section shows you the list of tablespaces for the database. The following information is presented for each tablespace:

- **Tablespace Details**
- **Container Details**

### Tablespace Details

- **ID:** Internal DB2 Tablespace identifier.
- **Name:** Tablespace Name
- **Type:** Tablespace Type – SMS (System Managed Space) or DMS (Database Managed Space)
- **Content Type:** Shows the type of data that can be stored on the tables pace. The valid types are:
  - Any meaning can store any type of data
- Sys Temp meaning, used internally by DB2 to store intermediate result data
- User Temp meaning, can be used to create temporary tables
- Long meaning, can be used to store LOB/LONG/Index data

- **State:** Can be one or more of the following:
  - Normal (see the definition SQLB_NORMAL in sqlutil.h)
  - Quiesced: SHARE
  - Quiesced: UPDATE
  - Quiesced: EXCLUSIVE
  - Load pending
  - Delete pending
  - Backup pending
  - Roll forward in progress
  - Roll forward pending
  - Restore pending
  - Recovery pending (not used)
  - Disable pending
  - Reorg in progress
  - Backup in progress
  - Storage must be defined
  - Restore in progress
  - Offline and not accessible
  - Drop pending
  - Storage may be defined
  - Storage Definition is in ‘final’ state
  - Storage Definition was changed prior to rollforward
  - DMS rebalancer is active
  - TBS deletion in progress
  - TBS creation in progress

- **Page Size:** The size of tablespace pages
Space View (DB2 LUW Performance Analyst)

- **Extent Size**: Number of pages that will be written to a container before writing to the next container on the tablespace.
- **Prefetch Size**: The maximum number of pages the prefetcher gets from the disk at a time.
- **Usable Space**: The total space in a table space minus overhead space. (Note: For SMS tablespaces, this element will have the same value as Used Space).
- **Used Space**: The total space in the tablespace that is currently used in the tablespace (including overhead).
- **Free Space**: The total space that is free to be used for storage of data. This element is not applicable for SMS tablespace. Free space for an SMS tablespace is the OS file system free space for the SMS containers.
- **Total Space**: The total space used by the tablespace.
- **Pending Free Pages**: The number of pages in the tablespace that would become free if all pending transactions are committed or rolled back and new space is requested for an object. (Applies only to DMS tablespaces)
  1. **Containers**: The number of containers in the tablespace.
- **Usable Pages**: The total pages in a table space minus overhead pages. (Note: For SMS tablespaces, this element will have the same value as Used Pages).
- **Used Pages**: The total pages in the tablespace that is currently used in the tablespace (including overhead).
- **Free Pages**: The total pages that are free to be used for storage of data. This element is not applicable for SMS tablespace. Free pages for an SMS tablespace are dependent on the OS file system free space for the SMS containers.
- **Total Pages**: The total pages used by the tablespace.
- **Page HW**: For DMS, this element represents the page number of the first free extent following the last allocated extent of a table space. Note that this is not really a "high water mark", but rather a "current water mark", since the value can decrease. For SMS, this is not applicable.

### Container Details

This section shows the list of containers for the selected tablespace. The information presented here includes:

- **ID**: A value that uniquely identifies the container within the tablespace.
- **Name**: The name of the container. Typically this is the full path of the file/directory/device where the container exists.
Type: The type of container. An SMS Container will be a directory. A DMS Containers will be a raw device/file/stripped disk/ or stripped file. Together with Container name, and partition, this metric identifies the physical location of the container.

DB Partition: The database partition where the container exists

Usage Pages: Usable pages in the container (Applicable to DMS Tablespaces only).

Total Pages: Total pages in the container

Stripe Set: The stripe set that a container belongs to.

Accessible: This element describes if a container is accessible or not

Location IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Usage tab

Metrics This section can be used to get a better understanding of the physical layout of a tablespace. Also, it lets you quickly identify if any containers are inaccessible.

Logging tab

The Logging tab of the Space Detail view displays Logging Space statistics:

- Log Read/Writes
- Indoubt Transactions
- Log Usage
- Secondary Logs

Log Read/Writes

This section shows the level of read/write activity being performed by the logger. The information presented here is:

- Log Reads: The number of log pages read from the disk by the logger per second.
- Log Writes: The number of log pages written to the disk by the logger.

Location IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Logging tab

Metrics You can use this page with the operating system level I/O metrics, to quantify the amount of I/O on a device that is attributable to database activity.

Indoubt Transactions

This section shows the number of outstanding indoubt transactions in the database.
Location IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Logging tab

Metrics Indoubt transactions hold log space for uncommitted transactions, which can cause the logs to become full. When the logs are full, further transactions cannot be completed. The resolution of this problem involves a manual process of heuristically resolving the indoubt transactions. This monitor element provides a count of the number of currently outstanding indoubt transactions that must be heuristically resolved.

Log Usage

This section shows the following log usage details:

- **Total Used Space**: Total space used by log files
- **Total Free Space**: Total space still available to the logger
- **Total Used Space Highwatermark**: The maximum amount of total log space used.
- **Secondary Space Used High Watermark**: The maximum amount of secondary log space used.

Location IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Logging tab

Metrics Use these metrics to check your current log space usage and the highest amount of space used by the logger. If the usage is high and the high watermarks are also near the total available space, you may need to increase the amount of log space or end/commit/rollback the oldest transaction.

Correction You can use the following database configuration parameters to change the amount of log space available: `logfilsiz`, `logprimary`, and `logsecond`. You can end (force) a connection with a long running transaction using the DBArtisan database monitor.

Secondary Logs

This section shows the secondary logs allocations by the database over the monitoring period.
Space View (DB2 LUW Performance Analyst)

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Logging tab

Metrics  When the primary log files become full, the secondary log files are allocated one at a time as needed, up to a maximum number as controlled by the logsecond database configuration parameter. Secondary log files are useful in preventing occasional log fill ups but they may not be as efficient as primary log and they also increase the recovery time. If you see a constant reliance on secondary log files, it may indicate infrequent commits by database applications or insufficient primary log space.

Correction  First examine the database applications to see if secondary log files are due to long running transactions and whether these transactions can be shortened. If the transactions cannot be shortened or you still see a very frequent use of secondary logs after transaction tuning, increase the primary log size (logprimary,logfilsiz Database configuration parameters) to reduce the dependence on secondary logs. If there is an occasional long running transaction, and you see your see transaction log full (SQL0964C) error messages, you can either increase the number of secondary log files (logsecond database configuration parameter) or set the number to -1 (no limit on number of secondary log files).

Bufferpools tab

The Bufferpools tab of the Space Detail View shows the list of tablespaces, with the current bufferpool associated with each tablespace and also the bufferpool used by the database at next startup.

Objects tab

The Objects tab of the Space Detail View shows the following statistics:

- Tablespace Object Summary
- Tablespace Object Details

Tablespace Object Summary

This section shows information about how tablespaces are being used on the database. The information presented here includes:

- Tablespace: Name of the tablespace
- Table Count: Number of tables on the tablespace
- Page Size: Tablespace page size
- Index Count: Number of indexes on the tablespace
- Table Space: Space used by tables on the tablespace
- Index Space: Space used by indexes on the tablespace
Tablespace Object Details

This section shows the details of the objects on the tablespaces shown in the Tablespace Object summary section. The user can toggle between the list of tables and indexes for the tablespace.

The information presented here for tables includes:

- **Table Schema**: Schema name of the table
- **Table Name**: Name of the tables
- **Avg Row Length**: Approximate length of the table row.
  1. Rows: Table Cardinality
  2. Pages Allocated: Number of pages allocated to the table
- **Table Size**: Total space used by the rows on the table
- **Available**: Total available space on the table
- **Total**: Total space used by the table pages

**Note**: The information presented here is based on the table/index statistics and if the statistics haven’t been collected /updated, this information may be out of date.

Quiesce tab

The Quiesce tab of the Space Detail view shows displays the following information:

- **Quiesced Tablespaces**
- **Quiescer Details**

Quiesced Tablespaces

This section shows a list of quiesced tablespaces. A quiesce is a persistent lock. Its benefit is that it persists across transaction failures, connection failures, and even across system failures (such as power failure, or reboot).
Location | IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Quiesce tab

Metrics | A quiesce is owned by a connection. If the connection is lost, the quiesce remains, but it has no owner, and is called a phantom quiesce. For example, if a power outage caused a load operation to be interrupted during the delete phase, the tablespaces for the loaded table would be left in delete pending, quiesce exclusive state. With a database restart, this quiesce would be an unowned (or phantom) quiesce. The removal of a phantom quiesce requires a connection with the same user ID used when the quiesce mode was set. This section is useful in identifying the tablespaces that are in a quiesced state.

Correction | To remove a phantom quiesce: Connect to the database from DBArtisan with the same user ID used when the quiesce mode was set. Re-quiesce the table space using the current quiesce state from DBArtisan. Reset the quiesce from DBArtisan.

Quiescer Details

This section shows the list of quiescers for the selected quiesced table.

Location | IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Quiesce tab

Metrics | Any quiescers whose agent ids are not listed under Users Detail >Attributes are phantom.

Correction | To remove a phantom quiesce: Connect to the database from DBArtisan with the same user ID used when the quiesce mode was set. Re-quiesce the table space using the current quiesce state from DBArtisan. Reset the quiesce from DBArtisan.

Rebalance tab

The Rebalance tab of the Space Detail page displays the following information:

- Rebalance Status

The following statistic, available on this pane, are duplicates of statistics on the Space View (DBArtisan - DB2 LUW Performance Analyst) Usage tab.

Tablespace Details

Rebalance Status

This section shows a graph of the percentage of extents that have been processed and the percentage that remains incomplete for the selected tablespace.
Reorganization tab

The Reorganization tab of the Space Details View displays the following statistics:

- **Table Details**
- **Reorganization Status**
- **Reorganization Attributes**

**Table Details**

This section shows the details of all the tables on which reorganization has been attempted since the start of monitoring. It also shows the status of tables that are presently undergoing reorganization. The information presented in this includes:

- **Table Schema**: Table Schema of the table on which reorganization is being/was performed
- **Table Name**: Table Name of the table on which reorganization is being/was performed
- **Tablespace**: Tablespace of the table on which reorganization is being/was performed
- **Start**: Start time of the reorganization
- **End**: End Time of the reorganization
- **Phase Start**: Start time of a phase of reorganization
- **Current Counter**: Percentage of reorganization operation completed (0 if the reorganization status is complete)
- **Max Phase**: The maximum number of reorganization phases that will occur during reorganization processing. This applies to classic (offline) reorganizations only.
- **Status**: The status of an in-place (online) table reorganization. This is not applicable to classic (offline) table reorganizations. An in-place table reorganization can be in one of the following states:
  - Started/Resumed
  - Paused
  - Stopped
  - Completed
Space View (DB2 LUW Performance Analyst)

- Truncate
  - **Completion**: Table reorganize success indicator.
  - **Phase**: Table reorganize phase. This applies to classic (offline) table reorganizations only.
  - For classic table reorganization, the following phases are possible:
    - Sort
    - Build
    - Replace
    - Index Recreate
  - **% Complete**: Shows the completion status of the reorganization jobs

**Location** [IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Reorganization tab]

### Reorganization Status

Shows a graphical status view of the currently selected reorganization.

**Location** [IBM DB2 (W/U/L) Performance Analyst statistics > Space View (DBArtisan - DB2 LUW Performance Analyst) > Reorganization tab]

### Reorganization Attributes

This section shows the reorganization attributes of the currently selected reorganization. The attributes include:

- Allow Write Access
- Allow Read Access
- Allow No Access
- Recluster Via Index Scan
- Reorg Long Field LOB Data
- No Table Truncation
- Reclustering
- Reclaiming
- Inplace Table Reorg
- Table Reorg
- Recluster Via Table Scan
Reorg Data Only.

Location [IBM DB2 (W/U/L) Performance Analyst statistics] > Space View (DBArtisan - DB2 LUW Performance Analyst) > Reorganization tab

Rollforward tab

Recovering database changes is time-consuming. You can use the database system monitor to monitor the progression of a recovery. This section provides the following elements to help you monitor the status of rollforwards:

- **Timestamp**: Timestamp of the log being processed. This is an indicator of the data changes that will be recovered
- **Tablespace**: Tablespace being rolled forward. This element identifies the tablespaces involved in the rollforward
- **Type**: An indicator of whether the recovery is happening at a database or tablespace level
- **Log#**: The log being currently processed. This identifies the log involved in the rollforward.
- **Status**: The status of rollforward recovery. This metric indicates if the recovery is in an undo (rollback) or redo (rollforward) phase.
  - 1. **Tablespaces**: Number of tablespaces involved in the rollforward
- **Node**: Indicates the database partition number for the rollforward operation
Users View (DB2 LUW Performance Analyst)

The database activity can be examined using key performance metrics and wait/bottleneck-based analysis. In addition to a Home page, the Users category of DB2 Performance Analyst includes the following tabbed pages:

- Top Sessions tab
- Cursors tab
- SQL Activity tab
- Attributes tab
- Lock Waits tab
- Locks tab

Home

The Home page of the Users performance category view displays the vital DB2 user statistics in the following categories:

- Key User Analysis Pane
- Bottleneck Analysis Pane
- SQL Analysis Pane
- Connection Analysis Pane

Key User Analysis Pane

Database performance analysts typically use one of two methods for examining the performance levels of a database - ratio-based or wait/bottleneck-based. Ratio-based analysis involves examining a number of key database ratios that can be used to indicate how well a database is running. Performance ratios serve as very good roll-up mechanisms for busy DBAs to use for at-a-glance performance analysis. Many DBAs have large database farms to contend with and cannot spend time checking detailed wait-based analysis outputs for each and every database they oversee. Succinctly presented performance ratios can assist in such situations by giving DBAs a few solid indicators that can be quickly scanned to see if any database needs immediate attention.

While there are certainly many opinions as to what rules to follow, there are some standards that should always be adhered to. To start with, many of the formulas that make up ratio-based analysis must be derived from delta measurements instead of cumulative statistics. Many of the global ratios that a DBA will examine come from the DB2 Snapshot Monitor. The snapshot monitor returns metrics for the Instance and
particular databases since the start of monitoring. Some metrics are cumulative (e.g., counters) and others are instantaneous (e.g., gauges).

A final thing to remember about using ratio-based analysis is that, while there are a number of rules of thumb that can be used as starting points to begin the evaluation of database performance, DBAs must determine each SQL Server's individual 'personality' with respect to the key performance ratios. Some hard and fast rules simply do not apply to every database. The danger in using blanket ratio standards is that they can lead the DBA to haphazardly take action, which can at times contribute nothing to the situation, and sometimes even degrade performance.

The following ratios are used on the Performance Analyst User page to succinctly communicate the general overall performance levels of the monitored database:

- **Efficiency**
  - Transactions/sec
  - Static SQL/sec
  - Dynamic SQL/sec

- **Activity**
  - Applications Executing
  - Connections High Watermark

### Transactions/sec

Transactions/sec is the number of transactions (units of work) completed per second on the database.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Key User Analysis Pane

**Metrics**  
A small rate of transactional activity on the database can indicate that applications are not doing frequent commits, which may lead to logging and concurrency problems.

**Correction**  
Drill down to the Users Detail>SQL Activity page to check which applications are running their transactions for long periods of time

### Static SQL/sec

The static SQL/sec metric is the number of static SQL statement executions attempt on the database each second.
Dynamic SQL/sec

This metric is the number of dynamic SQL statement executions being attempted on the database each second.

Applications Idle

The idle applications metric indicates the number of applications that are currently connected to the database for which the database manager is not executing any requests.

Applications Executing

The executing applications statistic indicates the number of applications for which the database manager is currently executing requests.

Connections High Watermark

The connections high watermark is the highest number of simultaneous connections to the database since the database was activated.
Users View (DB2 LUW Performance Analyst)

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Key User Analysis Pane

Metrics  You can use this element to evaluate the setting of the maxappls configuration parameter. If the value of this element is the same as the maxappls parameter, it is likely that some database connection requests were rejected, since maxappls limits the number of database connections allowed.

Correction  Increase the value of the maxappls parameter to allow more connections.

Bottleneck Analysis Pane

When a DB2 database is active, the applications accessing the database can either successfully access the database resources, or they can wait for resources to become available. An application that is waiting can indicate normal database activity, or it can be an indicator that a database bottleneck exists. This is where wait-based or bottleneck analysis comes into play. A database administrator can use this form of performance analysis to determine if perceived bottlenecks in a database are contributing to a performance problem.

Performance Analyst Bottleneck analysis section helps a DBA isolate potential problem areas where there are waits, resource overloads or potential failures. If concurrency issues or heavy table scan activity has been dragging a database’s performance down, a DBA can use bottleneck analysis to isolate the root cause. Once one or more bottlenecks have been isolated as possible areas of interest, the DBA can drill down and examine details on why the applications or resources are causing the problem. The Performance Analyst Users page identifies the top system and application bottlenecks that may be currently a cause of lessened performance.

The following bottleneck indicators are used on the Performance Analyst Home page to succinctly communicate the general overall performance level of the monitored database:

- Top Bottlenecked User Processes
- Automatic Rebinds
- Internal Rollbacks
- Waits
- Deadlocks
- Timeouts

The following statistics, appearing on this page, duplicate statistics available on the Bottleneck Analysis Pane of the Home View (DB2 LUW Performance Analyst) page:

- Lock Escalations
- Sort Overflows
- Failed SQL
The following statistic, available on this pane, duplicates a statistic on the SQL Analysis Pane of the Home View (DB2 LUW Performance Analyst) page:

- Failed SQL

### Top Bottlenecked User Processes

The top bottlenecked user processes grid shows the top bottlenecked applications in the system. These applications are either performing the top I/O operations or have idled the longest to obtain locks.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

### Automatic Rebinds

The automatic rebinds statistic is the number of automatic rebinds (or recompiles) that have been attempted.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  
Automatic rebinds are the internal binds the system performs when an package has been invalidated. The rebind is performed the first time the database manager needs to execute an SQL statement from the package. For example, packages are invalidated when you: Drop an object, such as a table, view, or index, on which the plan dependsAdd or drop a foreign keyRevoke object privileges on which the plan depends. Since automatic rebinds can have a significant impact on performance, they should be minimized where possible.

### Internal Rollbacks

The internal rollbacks statistic is the total number of rollbacks initiated internally by the database manager.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics**  
An internal rollback occurs when any of the following cannot complete successfully: A reorganizationAn importA bind or pre-compileAn application ends as a result of a deadlock situation or lock timeout situationAn application ends without executing an explicit commit or rollback statement (on Windows).

### Waits

The lock waits metric is the total number of times that applications or connections waited for locks within the database.
Deadlocks

The deadlocks statistic is the total number of deadlocks that have occurred since this instance of Performance Analyst started monitoring the database.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics** If a large number of deadlocks are detected, it can indicate that applications are experiencing lock contention problems. Deadlocks are usually caused by one of the following situations:
- Lock escalations on the database
- Catalog tables locked for Repeatable Read
- Applications are using inappropriate isolation levels at bind time
- Applications are obtaining the same locks in a different order
- Applications are locking tables explicitly where row level locks are sufficient.

**Correction** You may be able to modify the applications causing lock contentions for better concurrency. To identify the applications that may be causing contentions, go to the Lock Waits tab of the Users detail page and review the Application Details section.

Timeouts

The lock timeouts metric identifies the number of times that a request to lock an object timed out without being granted.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

**Metrics** If the number of lock timeouts becomes excessive when compared to the acceptable range for your database, it can indicate that an application is holding locks for long durations. It can also indicate that the amount of time an application waits for a lock before timing out is too short. If you have too few lock timeouts and the average lock wait time is too short, it can indicate that the lock timeout configuration parameter is set to an excessively high value.

**Correction** First you should examine the lock activity at the application level (Users>Lock, Lock Waits drilldown) to identify any particular application that is causing excessive lock contentions. If so, you can tune the application to provide better concurrency. If lock timeouts are excessive, and average lock wait times are very short, you can increase the locktimeout database configuration parameter to make the applications wait longer before timing out.

SQL Analysis Pane

Most of database’s I/O performance can be attributed to SQL statement execution. Poorly optimized SQL statements can drag down an otherwise well-configured server in terms of user response times.
This section shows a snapshot of row level SQL operations that have been performed on the database since you started monitoring. This gives you an insight into the row level of read/write activity that is currently occurring within the database and comparing this to the prefetcher, and cleaner activity allows you to relate the two.

The following statistics are used on the Performance Analyst for DB2 User home page to succinctly communicate the general overall performance levels of I/O. They duplicate statistics appearing on the SQL Analysis Pane of the I/OHome page:

- Rows Deleted
- Rows Inserted
- Rows Selected
- Rows Updated
- Rows Read

**Connection Analysis Pane**

The Connection Analysis section displays the level of application connect/disconnect activity occurring on the database.

The following statistics are used on the Performance Analyst for DB2 User home page to succinctly communicate general overall connectivity:

- Current Connections
- Disconnects
- Connections Since Database Activation
- High Watermark for Concurrent Connections

**Current Connections**

The current connections metric is the number of applications currently connected to the database.
Users View (DB2 LUW Performance Analyst)

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Connection Analysis Pane

Metrics  You can use this metric to help you get an overview of the level of database activity and the amount of system resources in use.

Correction  This metric can help you adjust the setting of the maxappls and max_coordagents configuration parameters. For example, if this value is always the same as maxappls, you consider increasing the value of maxappls.

Disconnects

This metric shows the number of disconnects from the database since the first connect, activate, or last reset.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Connection Analysis Pane

Connections Since Database Activation

The connections since database activation statistic indicates the number of connections to the database since the first connect, activate, or last reset.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Home > Connection Analysis Pane

Metrics  Use this metric in conjunction with the database connection time and the database start time to see if the application connection frequency is low. When there are no connections to db2, by default the database is automatically deactivated until the next connection. The connection that reactivates the database encounters slow connection time because it needs to wait for the database to reinitialize. If very few applications are connecting to the database, some connections can be slow because of this

Correction  If there are short periods when your database has no applications connected to it, activate the database explicitly using the ACTIVATE DATABASE command. This significantly improves the connection performance for the database.

High Watermark for Concurrent Connections

The connections high watermark is the highest number of simultaneous connections to the database since the database was activated.
You can use this element to evaluate the setting of the maxappls configuration parameter. If the value of this element is the same as the maxappls parameter, it is likely that some database connection requests were rejected, since maxappls limits the number of database connections allowed.

**Correction** Increase the value of the maxappls parameter to allow more connections.

**Workload Analysis Pane**

When your phone starts ringing with complaints of performance slowdowns, one of the first things you should get a handle on is:

- Who is currently connected to the database?
- What resources are they using?
- What are they currently executing?

The Workload Analysis section of the Performance Analyst Users page provides insight into the leading resource hogs of a server. Drill-downs are available so you can easily get detailed information into what each leading application is currently involved with. The Workload Analysis section presents the following metrics:

- **Top Lock Escalations** The top lock escalation displays the application with largest number of lock escalations.
- **Top CPU Process** The top CPU process displays the application with the highest CPU usage.
- **Top I/O Process** The top I/O process displays the application with the highest I/O read/write time.
- **Oldest Transaction** The oldest transaction displays the application with the longest running current transaction.

**Top Sessions tab**

Very often, one renegade client application brings a healthy database down by hogging most of the available resources. This page shows the top resource hogs in each of the resource usage areas to help you quickly identify the worst offenders in each area. You see:

- **Top I/O Process**
- **Top Memory Process**
- **Top CPU Process**
- **Top Sessions**
Top I/O Process

This section shows the application with the top IO time and compares it with the IO time of all other applications.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Top Sessions tab

Metrics  The metrics are calculated by measuring the total time spent by each application doing reads and writes (buffered and non-buffered).

Top Memory Process

This section shows the application with the largest memory pool usage aggregate. It also shows the total memory pool usage for all other applications.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Top Sessions tab

Metrics  This metric is calculated by aggregating all of the memory pools for each application and showing the top application. This section is useful in determining if the top application is using a lot more resources.

Top CPU Process

This section shows the application with the top CPU time usage and compares it with the CPU usage of all other applications.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Top Sessions tab

Metrics  Metrics are calculated using the total user and system CPU time for each application connected to the database.

Top Sessions

Shows a list of all applications connected to the database and the resource usage for these applications. The information presented for each application includes:

- **Auth ID:** The authorization ID of the user who invoked the application that is being monitored
- **Name:** The name of the application running at the client as known to the database manager
- **Handle:** A system-wide unique ID for the application. On a single-partitioned database, it consists of a 16 bit counter. On a multi-partitioned database, it consists of the coordinating partition number concatenated with a 16 bit counter. In addition, this identifier will be the same on every partition where the application may make a secondary connection.
Users View (DB2 LUW Performance Analyst)

- **ID**: This identifier is generated when the application connects to the database at the database manager.
- **Client PID**: The process ID of the client application that made the connection to the database.
- **I/O Time**: The total time spent by application in performing buffered and non-buffered reads and writes.
- **Memory Usage**: Total memory pool usage for the application.
- **CPU Time**: The total user + system CPU time used by the application agents.
  
  1. **Agents**: Number of agents for the application.

- **Status**: Current Status of the application. Values for this field are:
  
  - Database Connect Pending: The application has initiated a database connection but the request has not yet completed.
  - Database Connect Completed: The application has initiated a database connection and the request has completed.
  - Unit of Work Executing: The database manager is executing requests on behalf of the unit of work.
  - Unit of Work Waiting: The database manager is waiting on behalf of the unit of work in the application. This status typically means that the system is executing in the application’s code.
  - Lock Wait: The unit of work is waiting for a lock. After the lock is granted, the status is restored to its previous value.
  - Commit Active: The unit of work is committing its database changes.
  - Rollback Active: The unit of work is rolling back its database changes.
  - Recompiling: The database manager is recompiling (that is, rebinding) a plan on behalf of the application.
  - Compiling: The database manager is compiling an SQL statement or precompiling a plan on behalf of the application.
  - Request Interrupted: An interrupt of a request is in progress.
  - Database Disconnect Pending: The application has initiated a database disconnect but the command has not yet completed executing. The application may not have explicitly executed the database disconnect command. The database manager will disconnect from a database if the application ends without disconnecting.
  - Decoupled from Agent: The application has been decoupled from an agent.
• Transaction Prepared: The unit of work is part of a global transaction that has entered the prepared phase of the two-phase commit protocol.

• Transaction Heuristically Committed: The unit of work is part of a global transaction that has been heuristically committed.

• Transaction Heuristically Rolled Back: The unit of work is part of a global transaction that has been heuristically rolled-back.

• Transaction Ended: The unit of work is part of a global transaction that has ended but has not yet entered the prepared phase of the two-phase commit protocol.

• Creating Database: The agent has initiated a request to create a database and that request has not yet completed.

• Restarting Database: The application is restarting a database in order to perform crash recovery.

• Restoring Database: The application is restoring a backup image to the database.

• Backing Up Database: The application is performing a backup of the database.

• Data Fast Load: The application is performing a "fast load" of data into the database.

• Data Fast Unload: The application is performing a "fast unload" of data from the database.

• Wait to Disable Tablespace: The application has detected an I/O error and is attempting to disable a particular table space. The application has to wait for all other active transactions on the table space to complete before it can disable the table space.

• Quiescing a Tablespace: The application is performing a quiesce table space request.

• Wait for Remote Partition: The application is waiting for a response from a remote partition in a partitioned database instance.

• Remote Request Pending: The application is waiting for results from a federated datasource.

  o Last UOW Start Time: The date and time that the unit of work first required database resource

  o Last UOW End Time: The date and time that the most recent unit of work completed, which occurs when database changes are committed or rolled back

  o Current UOW Elapsed Time: The elapsed execution time of the most recently completed unit of work.

  o Login Timestamp: The date and time that a connection request was granted.
Users View (DB2 LUW Performance Analyst)

- **Inbound Comm Address**: This is the communication address of the client.
- **Client Protocol**: The communication protocol that the client application is using to communicate with the server.

Location: [IBM DB2 (W/U/L) Performance Analyst statistics] > Users View (DB2 LUW Performance Analyst) > Top Sessions tab

## Cursors tab

The Cursors tab of the Users Detail view displays the Application SQL Cursor Activity. It details the SQL cursors open for each application. The information presented here includes:

- **Open Cursors**: The number of cursors (local and remote) currently open for an application.
- **Blocking Cursors**: The number of blocking cursors (local and remote) currently open for the application.
- **Block Requests Accepted**: The percentage of all blocking I/O requests that were accepted by the database.
- **Block Requests Rejected**: The percentage of all blocking I/O requests that were rejected by the database.

### Metrics

The number of blocking cursors for an application should be close to the number of open cursors. If this is not the case, the application performance may be affected. If there are many cursors blocking data, the communication heap may become full. When this happens, instead of returning an error, the database stops allocating I/O blocks for blocking cursors.

### Correction

If the number of blocking cursors in an application is not close to the number of open cursors, you may be able to improve application performance by tweaking the precompile options for record blocking for the treatment of ambiguous cursors, and by redefining the cursors with FOR FETCH ONLY clause where possible.

If a large number of cursors were unable to perform blocking, you may be able to improve performance by increasing the query_heap database manager configuration parameter.

## SQL Activity tab

The SQL Activity tab of the Users Detail view displays the following statistics:

- **Application List**
- **SQL Executed**
Application List

This section shows a list of applications connected to the database. You can select an application from this list and see details for the SQL activity for this application.

Location IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > SQL Activity tab

SQL Executed

This section shows the details for the various types of SQL statements executed by the particular application. It also gives you the total application throughput. The information presented here includes:

- **Selects**: Percentage of statements that are select statements
- **Updates/Inserts/Deletes**: Percentage of statements that modify/write data on the database
- **DDLS**: Percentage of CREATE/DROP/ALTER statements
- **Others**: All other types of statements (Fetch, Open cursor etc)

Location IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > SQL Activity tab

Metrics Various types of statements have varying impact on the performance and concurrency of the database. For example - DDL statements can cause catalog and package cache invalidations, Insert/update/delete statements usually obtain locks and perform log IO. This section can help you determine the contributing statement types to the activity for an application.

SQL Activity

This section gives details on the sql activity for the selected application. It allows you to quick compare the number of static dynamic and failed sql statements with the overall application throughput. The metrics presented here include:

- **Static SQL**: The number of static SQL statements that the application tried to execute
- **Dynamic SQL**: The number of dynamic SQL statements that the application tried to execute
- **Failed SQL**: The number of SQL statements (static and dynamic) that the application tried to execute but failed
SQL Throughput: Number of SQL statements (dynamic and static) that the application executed successfully

Location IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > SQL Activity tab

Metrics These elements may help you determine the nature of the application. Failed SQL statements metric may also help identify the cause of poor performance on the database since failed statements mean time wasted by the database manager.

UOW Details

Shows the units of work being completed by the application over the refresh time interval.

Location IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > SQL Activity tab

Metrics A low rate of unit of work completion may be an indicator of one of the following:

The application is not committing transactions frequently and may be causing concurrency issues for other applications
The application is idling and not performing any work on the server

Correction Examine the locks obtained by the application (Users Detail >Locks page) to see if a low number here should be a cause for concern.

Binds and Precompiles Executed

This section shows the total number of implicit and explicit binds and precompiles executed by the application.

Implicit rebinds are performed by the system when the application tries to execute a sql statement from a package and the package has been invalidated. A package is usually invalidated when you perform DDL/DCL operations on objects on which the package plan is dependent. Explicit rebinds occur when the user executes the REBIND PACKAGE command.

Location IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > SQL Activity tab

Metrics Bind and precompile operations have significant overhead for the database operations and they should be minimized during periods of heavy usage when possible.

Attributes tab

The Attributes tab of the Users Detail page displays the following statistics:

- Application List
- Application Attributes
Application List

This section shows the list of applications connected to the database. The user can obtain further details for an application from other sections on this page by selecting the application from this list.

Location: IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Attributes tab

Application Attributes

Shows the main information for the selected application. This information is useful in determining the applications connection attributes and its state. The information shown here includes:

- **Application Status**: The status of the application. Values for this field are:
  - Database Connect Pending: The application has initiated a database connection but the request has not yet completed.
  - Database Connect Completed: The application has initiated a database connection and the request has completed.
  - Unit of Work Executing: The database manager is executing requests on behalf of the unit of work.
  - Unit of Work Waiting: The database manager is waiting on behalf of the unit of work in the application. This status typically means that the system is executing in the application’s code.
  - Lock Wait: The unit of work is waiting for a lock. After the lock is granted, the status is restored to its previous value.
  - Commit Active: The unit of work is committing its database changes.
  - Rollback Active: The unit of work is rolling back its database changes.
  - Recompiling: The database manager is recompiling (that is, rebinding) a plan on behalf of the application.
  - Compiling: The database manager is compiling an SQL statement or precompiling a plan on behalf of the application.
  - Request Interrupted: An interrupt of a request is in progress.
  - Database Disconnect Pending: The application has initiated a database disconnect but the command has not yet completed executing. The application may not have explicitly executed the database disconnect
command. The database manager will disconnect from a database if the application ends without disconnecting.

- Decoupled from Agent: The application has been decoupled from an agent.
- Transaction Prepared: The unit of work is part of a global transaction that has entered the prepared phase of the two-phase commit protocol.
- Transaction Heuristically Committed: The unit of work is part of a global transaction that has been heuristically committed.
- Transaction Heuristically Rolled Back: The unit of work is part of a global transaction that has been heuristically rolled-back.
- Transaction Ended: The unit of work is part of a global transaction that has ended but has not yet entered the prepared phase of the two-phase commit protocol.
- Creating Database: The agent has initiated a request to create a database and that request has not yet completed.
- Restarting Database: The application is restarting a database in order to perform crash recovery.
- Restoring Database: The application is restoring a backup image to the database.
- Backing Up Database: The application is performing a backup of the database.
- Data Fast Load: The application is performing a “fast load” of data into the database.
- Data Fast Unload: The application is performing a “fast unload” of data from the database.
- Wait to Disable Tablespace: The application has detected an I/O error and is attempting to disable a particular table space. The application has to wait for all other active transactions on the table space to complete before it can disable the table space.
- Quiescing a Tablespace: The application is performing a quiesce table space request.
- Wait for Remote Partition: The application is waiting for a response from a remote partition in a partitioned database instance.
- Remote Request Pending: The application is waiting for results from a federated datasource.

o **ID of code page used by the application:** The code page identifier.

o **Application status change time:** The date and time the application entered its current status.
- **Sequence Number**: This is incremented whenever a unit of work ends (that is, when a COMMIT or ROLLBACK terminates a unit of work). Together, the application id and sequence number uniquely identify a transaction.

- **Client Product/Version ID**: The product and version of DB2 that is running on the client.

- **Database Alias used by the Application**: The alias of the database provided by the application to connect to the database.

- **User login id**: The ID that the user specified when logging into the operating system. This ID is distinct from auth_id, which the user specifies when connecting to the database.

- **DRDA correlation token**: The DRDA correlation token is used for correlating the processing between the application server and the application requester. It is an identifier dumped into logs when errors arise, that you can use to identify the conversation that is in error. In some cases, it will be the LUWID of the conversation.

- **Client operating platform**: The operating system on which the client application is running.

- **Database territory code**: The territory code of the database for which the monitor data is collected.

- **Application agent priority**: The priority of the agents working for this application.

- **Application priority type**: Operating system priority type for the agent working on behalf of the application.

- **Coordinating node**: In a multinode system, the node number of the node where the application connected or attached to the instance.

- **Connection request start timestamp**: The date and time that an application started a connection request.

- **Connection request completion timestamp**: The date and time that a connection request was granted.

- **Previous unit of work completion timestamp**: This is the time the unit of work completed.

- **Unit of work start timestamp**: The date and time that the unit of work first required database resources.

- **Unit of work stop timestamp**: The date and time that the most recent unit of work completed, which occurs when database changes are committed or rolled back.

- **Most recent unit of work elapsed time**: The elapsed execution time of the most recently completed unit of work.
- **Unit of work completion status:** The status of the unit of work and how it stopped.

- **Application idle time:** Number of seconds since an application has issued any requests to the server. This includes applications that have not terminated a transaction, for example not issued a commit or rollback.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Attributes tab

## Direct Authorities

Shows the highest level of direct authority granted to the application

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Attributes tab

## Indirect Authorities

Shows the highest level of indirect authority granted to the application

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Attributes tab

## Lock Waits tab

The Lock Waits tab of the Users Detail view shows the details for all applications in the database that are waiting on locks. This information is useful in tracking concurrency issues in the database. The statistics available here are:

- **Application Details**

- **Applications Waiting on Locks**

The following statistic, available on this tab, duplicates a statistic on the Bottleneck Analysis Pane of the Home View (DB2 LUW Performance Analyst) page:

- **Avg. Lock Wait Time**

## Application Details

This section shows the list of applications waiting for locks to be released on objects they need to access. The information presented here includes:

- **Auth ID:** The authorization ID of the user who invoked the application that is being monitored.

- **Name:** Name of the application executable

- **Handle:** A systemwide unique ID for the application
ID: This identifier is generated when the application connects to the database at the database manager

Client PID: The process ID of the client application that made the connection to the database

Total Lock Waits: The total number of times that applications or connections waited for locks

Total Lock Waiting Time: This is the total amount of elapsed time that this connection or transaction has waited for a lock to be granted to it.

Locks Waiting: Indicates the number of agents waiting on a lock

UOW Lock Waiting Time: The total amount of elapsed time current unit of work has spent waiting for locks

Wait Start Time: The date and time that this application started waiting to obtain a lock on the object that is currently locked by another application

Lock App Handle: System wide Unique ID of the application holding the lock

Lock App ID: ID of the application holding the lock

Lock Sequence ID: The sequence number of the application that is holding a lock on the object that this application is waiting to obtain.

Location: IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Lock Waits tab

Metrics: AuthID, Name, Handle, ID, and Client PID help you identify the application waiting on the lock. Lock App Handle, Lock App ID, and Lock Sequence number help you identify the application that is holding the waited on lock. You can use this information on Users Detail Locks tab to get further details on the application holding the locks and the locks it’s holding.

Correction: If an application is not performing well, and it has a high number of total lock waits, and a high total lock waiting time you may need to improve concurrency of the applications that are holding the locks.

Applications Waiting on Locks

This metric indicates the percentage of all connected applications waiting on locks.
Users View (DB2 LUW Performance Analyst)

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Users View (DB2 LUW Performance Analyst) > Lock Waits tab

Metrics  If this number is high, the application may have concurrency problems.

Correction  You can identify the applications that are holding locks or exclusive locks for a long time from the Users Detail> Locks page and tune such applications for better concurrency.

Locks tab

The Locks tab of the Users Detail view gives you information for the following statistics:

- Application Details
- Locks Held Details
- Locks Waiting Details

Application Details

This section shows a list of applications connected to the database. You can look at the lock details for an application in the list by selecting the application. The attributes presented for each application include:

- Handle: A system-wide unique ID for the application
- ID: This identifier is generated when the application connects to the database at the database manager
- Seq No
- Name: Name of the application executable
- Auth ID: The authorization ID of the user who invoked the application that is being monitored.
- Status
- Code Page
- Locks Held
- Total Wait Time
- UOW Lock Waiting Time
Locks Held Details

This section gives the details of all the locks that the selected application is currently holding. The details presented here include:

- **Lock Name**: Internal binary lock name. This element serves as a unique identifier for locks
- **Lock Attributes**: Gives the lock attribute settings
- **Release Flags**: The lock release flags can either be untracked or SQL Compiler
- **Lock Count**: The number of locks on the lock being held. This value ranges from 1 to 255. It is incremented as new locks are acquired, and decremented as locks are released. When lock_count has a value of 255, this indicates that a transaction duration lock is being held. At this point, lock_count is no longer incremented or decremented when locks are acquired or released. The lock_count element is set to a value of 255 in one of two possible ways:
  1. lock_count is incremented 255 times due to new locks being acquired.
  2. A transaction duration lock is explicitly acquired. For example, with a LOCK TABLE statement, or an INSERT.
- **Hold Count**: The number of holds placed on the lock. Holds are placed on locks by cursors registered with the WITH HOLD clause and some DB2 utilities. Locks with holds are not released when transactions are committed.
- **Object Name**: It is the name of the object for table-level locks is the file ID (FID) for SMS and DMS table spaces. For row-level locks, the object name is the row ID (RID). For table space locks, the object name is blank. For buffer pool locks, the object name is the name of the buffer pool.
- **Object Type**: The type of object against which the application holds a lock (for object-lock-level information), or the type of object for which the application is waiting to obtain a lock (for application-level and deadlock-level information).
- **Tablespace**: This is the name of the table space against which the lock is held.
- **Table Schema**: Schema of the table that the lock is on
- **Table Name**: Name of the table that the lock is on. This element is only set if Object Type indicates Table
- **Lock Mode**: The type of lock being held.
Locks Waiting Details

This section gives the details of all the locks that the selected application is currently waiting on. The details include:

- **Subsection**: Identifies the subsection associated with the waited on lock
- **Agent ID**: The application handle of the agent holding a lock for which this application is waiting
- **App ID**: The application ID of the application holding a lock on the object that this application is waiting to obtain.
- **Lock Name**: Internal binary lock name. This element serves as a unique identifier for locks.
- **Lock Attributes**: Gives the lock attribute settings
- **Release Flags**: Lock release flags
- **Object Type**: The type of object against which the application holds a lock
- **Lock Mode**: The type of lock being held
- **Lock Mode Requested**: The lock mode being requested by the application
- **Tablespace**: This is the name of the table space against which the lock is held.
- **Table Schema**: Schema of the table that the lock is on
- **Table Name**: Name of the table that the lock is on. This element is only set if Object Type indicates Table
- **Wait Start Timestamp**: The date and time that this application started waiting to obtain a lock on the object that is currently locked by another application
- **Escalation**: Indicates whether a lock request was made as part of a lock escalation.
Cfg (Configuration)

The Database Configuration view displays the following tabbed pages:

- Configuration tab
- History View (DB2 LUW Performance Analyst)
- Indoubt Transactions tab
- Objects tab

Configuration tab

This tab lets you view the current values for the DB2 database configuration parameters.
History View (DB2 LUW Performance Analyst)

The History tab of the Database Configuration Details viewlets you browse the history file entries for the database. The history file contains a record of recovery and administrative events. Recovery events include full database and table space level backup, incremental backup, restore, and rollforward operations. Additional logged events include create, alter, drop, or rename table space, reorganize table, drop table, and load.

History Details

This section allows you to select the operation for which you want to see the history details. You can also narrow the history list to operations since a certain date or operations involving a certain object name. You can show the history for the following types of operations:

- Backups
- Dropped Tables
- Load
- Quiesce
- Reorganizations
- Rollforward
- Tablespace Alters
- Tablespace Renames
- Tablespace Creates
- Tablespace Drops

You can see further detail on some operations in the lower sections, by selecting that operation from the history detail operation list.

- SQLCA Structure: Shows the SQLCA structure for the selected operation from the history detail. This information is not available for Quiesce, Rollforward, and Reorganization operations.
- Tablespaces List: Shows the list of tablespaces involved in the selected operation in history detail.
- DDL View: Shows the DDL for the selected operation in the history detail.

Indoubt Transactions tab

The Indoubt Transactions tab provides a list of transactions that are in doubt. The Indoubt Transaction Detail metrics displayed for each indoubt transaction include:

- **Application ID**: Specifies the application identifier assigned by the database manager for this transaction
- **Sequence Number**: Specifies the sequence number assigned by the database manager as an extension to the application ID
- **Status**: Indicates the status of this indoubt transaction. Valid values are:
SQLXA_TS_PREP  The transaction is prepared. The connected parameter can be used to determine whether the transaction is waiting for the second phase of normal commit processing or whether an error occurred and resynchronization with the transaction manager is required.

SQLXA_TS_HCOM  The transaction has been heuristically committed.

SQLXA_TS_HROL  The transaction has been heuristically rolled back.

SQLXA_TS_MACK  The transaction is missing commit acknowledgement from a node in a partitioned database.

SQLXA_TS_END  The transaction has ended at this database. This transaction may be re-activated, committed, or rolled back at a later time. It is also possible that the transaction manager encountered an error and the transaction will not be completed. If this is the case, this transaction requires heuristic actions, because it may be holding locks and preventing other applications from accessing data.

- **Timestamp**: Specifies the time when the transaction entered the indoubt state.
- **Auth ID**: Specifies the authorization ID of the user who ran the transaction.
- **Log Full**: Indicates whether or not this transaction caused a log full condition
- **Originator**
- **XID**: Specifies the XA identifier assigned by the transaction manager to uniquely identify a global transaction

**Objects tab**

Tables and indexes consume the storage in all databases. The Database Object Detail grid displays object space details for the database selected in the Database Object Summary grid.

The following statistics are presented for tables:

- **Table Schema**: The owner of the object
- **Table Name**: The name of the object
- **File Group**: File group where the object resides
- **Reserved (KB)**: The amount of space (in KB) reserved by the object
- **Used (KB)**: The amount of space (in KB) used by the object
- **Free (KB)**: The amount of free space (in KB) used by the object
- **Percent Used**: The percentage of space used by the object
Instance View (DB2 LUW Performance Analyst)

The Embarcadero Performance Analyst Instance view lets you review availability and overall performance of all monitored databases from a single window.

In addition to a Home page, the Instance category of DB2 Performance Analyst includes the following tabbed pages:

- Configuration tab
- Agents & Connections tab
- Utilities tab
- FCM Resources tab
- FCM Throughput tab
- Memory Pools tab
- Sorts & Joins tab

Home

Statistics on the Instance home view are organized into the following categories:

- Agent Analysis Pane
- Bottleneck Analysis Pane
- Instance Information Pane
- Key Ratio Analysis Pane

Agent Analysis Pane

The Agent Analysis section presents the following metrics:

- Connections
- Connections Executing
- Agents Registered
- Agents Waiting
- Idle Agents
Connections

The connections statistic gives the total number of connections to databases in the current instance.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > Home > Agent Analysis Pane

Metrics  Shows the number of connections from remote/local clients to databases in this instance. This changes frequently, so you may need to sample it at specific intervals over an extended period of time to get a realistic view of system usage.

Correction  This element can help you adjust the setting of the max_coordagents configuration parameter.

Connections Executing

The connections executing statistic is the number of applications that are currently connected to a database and are currently processing a unit of work within the Database Manager instance being monitored.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > Home > Agent Analysis Pane

Metrics  The connections executing metric can help you determine the level of concurrent processing occurring on the Database Manager. This value can change frequently, so you may need to sample it at specific intervals over an extended period of time to get a realistic view of system usage.

Correction  This element can help you adjust the setting of the maxcagents configuration parameter.

Agents Registered

The agents registered metric is the number of agents registered in the Database Manager instance that is being monitored (coordinator agents and subagents).

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > Home > Agent Analysis Pane

Correction  You can use this element to help evaluate your setting for the maxagents configuration parameter.

Agents Waiting

The number of agents waiting for a token so they can execute a transaction in the database manager.
Each application has a dedicated coordinator agent to process database requests within the Database Manager. Furthermore, each agent has to get a token before it can execute a transaction. The maximum number of agents that can execute Database Manager transactions is limited by the configuration parameter maxcagents.

Correction: You can use this element to help evaluate your setting for the maxcagents configuration parameter.

Idle Agents

The idle agents metric is the number of agents in the agent pool that are currently unassigned to an application and are, therefore, "idle."

Correction: You can use this element to help set the num_poolagents configuration parameter.

Bottleneck Analysis Pane

The Bottleneck Analysis section presents the following metrics:

- **Sorts and Joins**
  - Post Threshold Sorts
  - Piped Sorts Rejects
  - Hash Join Thresholds

- **Agent Bottlenecks**
  - Agents Waiting on a Token
  - Agents Created Due to Empty Pool

**Post Threshold Sorts**

This metric shows the number of sorts that have requested heaps after the sort heap threshold has been exceeded.
Metrics

Under normal conditions, the Database Manager allocates sort heap using the value specified by the sortheap configuration parameter. If the amount of memory allocated to sort heaps exceeds the sort heap threshold (sheapthres configuration parameter), the database manager allocates sort heap using a value less than that specified by the sortheap configuration parameter. Each active sort on the system allocates memory, which may result in sorting taking up too much of the system memory available. Sorts that start after the sort heap threshold has been reached may not receive an optimum amount of memory to execute. As a result, however, the entire system may benefit.

Correction

By modifying the sort heap threshold and sort heap size configuration parameters, the performance of sort operations and/or the overall system can be improved. If this element’s value is high, you can:

- Increase the sort heap threshold (sheapthres) or
- Adjust applications to use fewer or smaller sorts via SQL query changes.

Piped Sorts Rejects

The piped sorts rejects statistic is the number of piped sorts that were rejected by the database manager.

Correction

If piped sorts are being rejected, you might consider decreasing your sort heap or increasing your sort heap threshold. You should be aware of the possible implications of either of these options. If you increase the sort heap threshold there is the possibility that more memory will remain allocated for sorting. This could cause paging memory to disk. If you decrease the sort heap, you might require an extra merge phase that could slow down the sort.

Hash Join Thresholds

The hash join thresholds metric is the total number of times that a hash join heap request was limited because of concurrent use of shared or private sort heap.
Instance View (DB2 LUW Performance Analyst)

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Each active sort allocates memory, and can result in sorting taking up too much of the available system memory. A piped sort is not accepted if the sort heap threshold is exceeded when the sort heap is allocated for the sort. The sort list heap (sortheap) and sort heap threshold (sheapthres) configuration parameters help control the amount of memory used for sort operations. These parameters are also used to determine whether a sort will be piped. Since piped sorts may reduce disk I/O, allowing more piped sorts can improve the performance of sort operations and possibly the performance of the overall system.

Correction  If this value is large (greater than 5% of Hash Join Overflows), the sort heap threshold should be increased.

Agents Waiting on a Token

The agents waiting statistic is the percentage of agents registered that are waiting for a token so they can execute a transaction in the Database Manager.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > Home > Bottleneck Analysis Pane

Metrics  Each application has a dedicated coordinator agent to process database requests within the Database Manager. Each agent has to get a token before it can execute a transaction. The maximum number of agents that can execute database manager transactions is limited by the configuration parameter maxcagents. This parameter is used to control the load on the system during periods of high simultaneous application activity. For example, you may have a system requiring a large number of connections but with a limited amount of memory to serve those connections. Adjusting this parameter can be useful in such an environment, where a period of high simultaneous activity could cause excessive operating system paging. This parameter does not limit the number of applications that can have connections to a database. It only limits the number of Database Manager agents that can be processed concurrently by the Database Manager at any one time, thereby limiting the usage of system resources during times of peak processing.

Correction  In cases where the high concurrency of applications is causing problems, you can use benchmark testing to tune this parameter to optimize the performance of the database.

Agents Created Due to Empty Pool

The agents created due to empty pool metric shows the number of agents created because the agent pool was empty. It includes the number of agents started when the current instance started (num_initagents).
FCM Analysis Pane

The fast communication manager (FCM) provides communication support for Enterprise Server Editions. Each database partition server has one FCM thread to provide communications between database partition servers to handle agent requests and to deliver message buffers. The FCM thread starts when you start the instance.

The following ratios are used on the FCM Analysis section to succinctly communicate the general overall FCM performance levels of the monitored instance:

- **Buffer Throughput**
- **Buffer Utilization**
- **Connection Entry Utilization**
- **Message Anchor Utilization**
- **Request Block Utilization**

Buffer Throughput

The buffer throughput metric is the total number of buffers that have been sent and received by this database partition since the start of monitoring.

**Correction** If this traffic level is high, you should consider redistributing one or more databases on the instance or move tables to reduce internode traffic.

Buffer Utilization

This element indicates the percentage of all FCM buffers currently being used by the fast communication manager.
Connection Entry Utilization

The connection entry utilization element indicates the percentage of all connection entries that are currently being used by the fast communication manager.

Note: This metric is only applicable to DB2 version 7. In DB2 version 8, the maximum connection entries are adjusted dynamically and automatically.

Message Anchor Utilization

This metric shows the percentage of all message anchors currently being used by the fast communication manager.

Note: This metric is only applicable to DB2 version 7. In DB2 version 8, the maximum message anchors are adjusted dynamically and automatically.

Request Block Utilization

This element indicates the percentage of all request blocks that are currently being used by the fast communication manager.
Correction You can use this information to tune fcm_num_rqrb. If the utilization percentage is high, you should increase the fcm_num_rqrb to ensure that operations do not run out of FCM request blocks. If the utilization is low, you can decrease fcm_num_rqrb to conserve system resources.

Note: This metric is only applicable to DB2 version 7. In DB2 version 8, the maximum request blocks are adjusted dynamically and automatically.

Instance Information Pane

Here you see the following information:

- Product Name
- FixPack Level
- Instance Type
- Operating System
- Instance Name
- Number of Partitions
- Active Local Databases

Key Ratio Analysis Pane

The Key Ratio Analysis section presents the following metrics:

- Efficiency
  - Agents Registered
  - Agents Waiting
  - Monitor Heap
  - FCMBP
  - Private Sort Memory

Agents Registered

The agents registered metric shows the percentage of total allowable agents (coordinator agents and subagents) that are currently working in the instance.
Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > Home > Key Ratio Analysis Pane

Metrics  When this value is close to 100% it means that the number of agents currently working is close to the hard limit set in the database manager configuration. If this value stays high for long periods of time it means that there is high level of activity occurring in the databases on the instance.

Correction  Use this element to help you evaluate your setting for the maxagents database manager configuration parameter. When you increase the value of this parameter, make sure that your system has enough memory available to accommodate the additional agents that may be created.

Agents Waiting

The agents waiting statistic is the percentage of agents registered that are waiting for a token so they can execute a transaction in the Database Manager.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > Home > Key Ratio Analysis Pane

Metrics  Each application has a dedicated coordinator agent to process database requests within the Database Manager. Each agent has to get a token before it can execute a transaction. The maximum number of agents that can execute database manager transactions is limited by the configuration parameter maxcagents. This parameter is used to control the load on the system during periods of high simultaneous application activity. For example, you may have a system requiring a large number of connections but with a limited amount of memory to serve those connections. Adjusting this parameter can be useful in such an environment, where a period of high simultaneous activity could cause excessive operating system paging. This parameter does not limit the number of applications that can have connections to a database. It only limits the number of Database Manager agents that can be processed concurrently by the Database Manager at any one time, thereby limiting the usage of system resources during times of peak processing.

Correction  In cases where the high concurrency of applications is causing problems, you can use benchmark testing to tune this parameter to optimize the performance of the database.

Monitor Heap

This metric shows the percentage of total monitor heap that is currently being used by the Database Manager.
The amount of memory required for monitoring activity depends on the number of monitoring applications (applications taking snapshots or event monitors), which switches are set, and the level of database activity. Memory is allocated from the monitor heap when you perform database monitoring activities such as taking a snapshot, turning on a monitor switch, resetting a monitor, or activating an event monitor.

If this metric is running at over 70% utilization and you have many applications performing snapshot/event monitoring, you may need to increase the size of the monitor heap.

Correction: Increase the value of mon_heap_sz database manager configuration parameter to increase the available monitor heap size.

**FCMBP**

The fast communication manager bufferpool (FCMBP) is the percentage of total amount of the FCMBP that is currently being used. This metric is only applicable to multipartitioned database environments.

**Note:** FCM buffers are used for internal communication both among and within database servers. The FCMBU metric gives the percentage utilization of the available fcm buffers in the Database Manager.

**Private Sort Memory**

The private sort memory metric is the percentage of the total private sort memory heap that is currently in use.

**Configuration tab**

The Configuration tab of the Instance Detail view lets you view and change the instance configuration parameter. It also allows you to look at some information about the
instance such as Product Name, Type, Fixpak Level, Operating System, instance name, partitions, and number of active databases.

**Agents & Connections tab**

The Agents & Connections tab of the Instance Detail view gives you the following analyses:

- **Connection Analysis**
- **Agent Pool Analysis**
- **Agent Analysis**

**Connection Analysis**

This section presents the metrics for the current local and remote connections to databases in the instance. The information presented here includes:

- **Local Connections**: The number of local applications that are currently connected to a database within the database manager instance being monitored.

- **Remote Connections**: The current number of connections initiated from remote clients to the instance of the database manager that is being monitored.

- **Local Connections Executing**: The number of local applications that are currently connected to a database within the database manager instance being monitored and are currently processing a unit of work.

- **Remote Connections Executing**: The number of remote applications that are currently connected to a database and are currently processing a unit of work within the database manager instance being monitored.

**Agent Pool Analysis**

The metrics in this section help determine how often the database agents are created due to empty pool and how often they are assigned from the agent pool.
Agent Analysis

The metrics presented here give a detailed view of how the database manager agents are working. The metrics presented here include:

- **Registered Agents**: The number of agents registered in the database manager instance that is being monitored (coordinator agents and subagents).
- **Agents Waiting for Token**: The number of agents waiting for a token so they can execute a transaction in the database manager.
- **Idle Agents**: The number of agents in the agent pool that are currently unassigned to an application and are, therefore, "idle".
- **Stolen Agents**: The number of times that agents are stolen from an application. Agents are stolen when an idle agent associated with an application is reassigned to work on a different application.
- **Maximum Agents Registered**: The maximum number of agents that the database manager has ever registered, at the same time, since it was started (coordinator agents and subagents).
- **Maximum Agents Waiting**: The maximum number of agents that have ever been waiting for a token, at the same time, since the database manager was started.
- **Maximum Coordinating Agents**: The maximum number of coordinating agents working at one time.

Utilities tab

The Utilities tab of the Instance Detail View gives information on the utilities currently executing in the database manager. The Utility Execution Details are as follows:

- **Utility ID**: The unique identifier corresponding to the utility invocation
- **Type**: Class of the utility (Rebalance, Backup, Restore, Reorg etc.)
- **Utility Description**: A brief description of the work the utility is performing
Utility Start Time: The time the utility was invoked

DBName: Database on which the utility is operating.

FCM Resources tab

The FCM Resources tab of the Instances Detail View presents statistics on the following:

- Node Details
- FCM Buffer Utilization
- FCM Message Anchor Utilization
- FCM Connection Entries Utilization
- FCM Connection Entries Utilization

Node Details

This section gives a detailed view of inter-node communication in a multipartition environment. The information shown here includes the connection status and buffers sent and received between various combinations of partitions in a multi-partitioned environment. The columns presented here include:

- **Source Node**: Partition that sends the information
- **Target Node**: Partition that received the information
- **Buffers Sent**: Number of Buffers sent from source node to the target node
- **Buffers Received**: Number of Buffers sent from source node to the target node
- **Connection Status**

FCM Buffer Utilization

This section provides details on the current utilization and low watermark of FCM buffers.
Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > FCM Resources tab

Metrics  You can monitor the buffer utilization for the selected partition together with the low watermark to determine the usage trend of the fcm buffers.

Correction  If you notice a very small value for the low watermark and similar values for free FCM buffers over a long period, you may need to increase the fcm_num_buffers database manager configuration parameter to increase the number of available FCM buffers. If on the other hand you notice a very high value for the low watermark – you may have allocated too many buffers and you can reduce the value of fcm_num_buffers database manager configuration parameter.

FCM Message Anchor Utilization

This section provides details on the current utilization and low watermark of FCM message anchors.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > FCM Resources tab

Metrics  You can monitor the message anchor utilization for the selected partition together with the low watermark to determine the usage trend of the message anchors.

Correction  If you notice a very small value for the low watermark and similar values for free message anchors over a long period, you may need to increase the fcm_num_anchors database manager configuration parameter to increase the number of available message anchors. If on the other hand you notice a very high value for the low watermark – you may have allocated too many message anchors and you can reduce the value of fcm_num_anchors database manager configuration parameter.

FCM Connection Entries Utilization

This section provides details on the current utilization and low watermark of FCM connection entries.
Instance View (DB2 LUW Performance Analyst)

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > FCM Resources tab

Metrics You can monitor the connection entry utilization for the selected partition together with the low watermark to determine the usage trend of connection entries.

Correction If you notice a very small value for the low watermark and similar values for free connection entries over a long period, you may need to increase the fcm_num_connect database manager configuration parameter to increase the number of available connection entries. If on the other hand you notice a very high value for the low watermark – you may have allocated too many connection entries and you can reduce the value of fcm_num_connect database manager configuration parameter.

FCM Request Block Utilization

This section provides details on the current utilization and low watermark of FCM request blocks.

Location  IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > FCM Resources tab

Metrics You can monitor the request block utilization for the selected partition together with the low watermark to determine the usage trend of the request blocks.

Correction If you notice a very small value for the low watermark and similar values for free request blocks over a long period, you may need to increase the fcm_num_rqb database manager configuration parameter to increase the number of available request blocks. If on the other hand you notice a very high value for the low watermark – you may have allocated too many request blocks and you can reduce the value of fcm_num_rqb database manager configuration parameter.

FCM Throughput tab

The FCM Throughput tab of the Instance Detail View includes the following statistics:

- FCM Throughput

The following statistic, available on this tab, duplicates a statistic available on the Instance View (DBArtisan - DB2 LUW Performance Analyst) FCM Resources tab:

- Node Details

FCM Throughput

This section shows the delta statistics for the FCM buffers sent and received between the selected nodes in the Node Details section.
Location: IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > FCM Throughput tab

Metrics: If the total number of FCM buffers sent or received between selected nodes is high, you may want to redistribute the database, or move tables to reduce the inter-node traffic.

Memory Pools tab

The Memory Pools tab is divided into three panes. Unique to this tab is the Memory Pool List pane. The Memory Pool Details and the Memory Pool Utilization are duplicates of panes available in the Memory View (DB2 LUW Performance Analyst) category.

Memory Pool List pane

This section shows the memory pool usage details of the selected memory pool over time.

Sorts & Joins tab

The Sorts & Joins tab of the Instance Detail View presents the following information:

- Sort Heap Details
- Sort Threshold Details
- Hash Join Threshold Details
- Piped Sort Details

Sort Heap Details

This section shows the metrics for the total number of allocated pages of sort heap space for all sorts. It represents the sum of sort heap space allocated for all sorts in all active databases in the database manager.
Normal memory estimates do not include sort heap space. If excessive sorting is occurring, the extra memory used for the sort heap should be added to the base memory requirements for running the database manager. Generally, the larger the sort heap, the more efficient the sort. Appropriate use of indexes can reduce the amount of sorting required.

You may use the information in this section to help you tune the sheapthres configuration parameter. If the element value is greater than or equal to sheapthres, it means that the sorts are not getting the full sort heap as defined by the sortheap parameter.

**Sort Threshold Details**

This section details the number of sorts that have requested heaps after the sort heap threshold has been exceeded.

Under normal conditions, the database manager will allocate sort heap using the value specified by the sortheap configuration parameter. If the amount of memory allocated to sort heaps exceeds the sort heap threshold (sheapthres configuration parameter), the database manager will allocate sort heap using a value less than that specified by the sortheap configuration parameter. Each active sort allocates memory, which may result in sorting taking up too much of the system memory available. Sorts that start after the sort heap threshold has been reached may not receive an optimum amount of memory to execute, but, as a result, the entire system may benefit. By modifying the sort heap threshold and sort heap size configuration parameters, the performance of sort operations and/or the overall system can be improved.

If this element's value is high, you can: Increase the sort heap threshold (sheapthres) or, Adjust applications to use fewer or smaller sorts via SQL query changes.

**Hash Join Threshold Details**

This section shows the total number of times that a hash join heap request was limited due to concurrent use of shared or private sort heap space.
Piped Sort Details

This section gives the details on the piped sorts that have been requested and accepted.

Correction If piped sorts are being rejected, you might consider decreasing your sort heap or increasing your sort heap threshold. You should be aware of the possible implications of either of these options. If you increase the sort heap threshold, then there is the possibility that more memory will remain allocated for sorting. This could cause the paging of memory to disk. If you decrease the sort heap, you might require an extra merge phase that could slow down the sort.

Location IBM DB2 (W/U/L) Performance Analyst statistics > Instance View (DBArtisan - DB2 LUW Performance Analyst) > Sorts & Joins tab

Metrics Each active sort on the system allocates memory, which may result in sorting taking up too much of the available system memory. When the number of accepted piped sorts is low compared to the number requested, you can improve sort performance by adjusting one or both of the following configuration parameters: sortheap and sheapthres.
OS View (DB2 LUW Performance Analyst)

In many scenarios, an optimally tuned database may not perform well because there are constraints imposed by the system where the database is running. These constraints may include processes competing with the database server for resources (CPU, I/O, or Memory), a slow CPU, insufficient or slow I/O devices, and insufficient memory. The OS Statistics page of Performance Analyst lets you examine operating system metrics for the following platforms:

- AIX
- HP-UX

**Note:** To view processor info and swap disk info on an HP-UX box, you need to login as ROOT in the OS login.

- Linux
- Solaris
- Unix
- Windows XP and 2000

**Note:** The statistics available on the OS page depend on the operating system platform.

**Tip:** If you magnify a graph to change back to the original size or minimize the size, close the OS Page and then reopen it again. Performance Analyst displays the graph in its original form and size.

In addition to a Home page, the OS category of DB2 Performance Analyst includes the following tabbed pages:

- CPU Tab
- I/O Tab
- Memory Tab
- Network Tab
- Processes Tab
- Space Tab

**Home**

The OS home page includes the following sections:

- Key Resource Usage Pane
Key Resource Usage Pane

The following ratios are used on the Performance Analyst OS home page to communicate the general overall performance levels of the operating system:

- **Disk Time**
- **Load Average**
- **Processor Time**
- **Paged Memory Used** (Windows)
- **Swap Memory Used** (AIX, HP-UX, Linux, Solaris, Unix)

**Tip:** To open the CPU tab, right-click Processor Time. To open the I/O tab, right-click Disk Time. To open the Memory tab, right-click Paged Memory Used.

### Disk Time

The Disk Time statistic is the percentage of elapsed time that the selected disk drive/device was busy servicing read or write requests.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Key Resource Usage Pane

**Metrics**  
You should avoid consistently seeing values for this statistic greater than 90%.

**Correction**  
Add more disk drives and partition the files among all of the drives.

### Load Average

The Load Average statistic represents the system load averages over the last 1, 5, and 15 minutes.
High load averages usually mean the system is being used heavily and the response time is correspondingly slow.

**Processor Time**

The Processor Time statistic indicates the percentage of time the processor is working. This counter is a primary indicator of processor activity.

If your computer seems to be running sluggishly, this statistic could be displaying a high percentage.

**Correction**
Upgrade to a processor with a larger L2 cache, a faster processor, or install an additional processor.

**Paged Memory Used**

The Paged Memory Used statistic is the ratio of Commit Memory Bytes to the Commit Limit. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk. The commit limit is determined by the size of the paging file. As the paging file increases, so does the commit limit.

This value displays the current percentage value only and not an average. If the percentage of paged memory used is above 90%, you may be running out of memory.

**Correction**
Increase the size of page file.

**Note:** This statistic is available for the Windows platform.

**Swap Memory Used**

The Swap Memory Used statistic is the percentage of swap space currently in use.
Metrics If the percentage of swap memory used is above 90%, you may be running out of memory.

Correction Increase the size of your swap files.

Bottleneck Analysis Pane

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Average Disk Queue Length
- Interrupts/Sec
- Network Output Queue Length/Network Queue Length
- Page Faults/Sec
- Processor Queue Length
- Processor Speed
- Processor

Tip: To open the I/O tab, right-click any Details menu item. To open the CPU tab, right-click the Item Processor Queues Length Details menu item. To open the Network tab, right-click Network Output Queues Length.

Note: The statistics available in this section depend on the platform of operating system.

Average Disk Queue Length

The Average Disk Queue Length statistic is the average number of both read and write requests that were queued for the selected disk during the sample interval.
Metrics: This metric is useful in identifying I/O related bottlenecks. If the disk queue lengths for certain disks are consistently much higher than others, you may need to redistribute the load among available disks. If the disk queues lengths for all disks are consistently large, and you see a high amount of I/O activity, your disks may be inefficient.

Correction: Some things you can do if you have problems with this statistic include: Redistribute the data on the disk with the large average disk queue to other disks. Upgrade to faster disk(s).

Interrupts/Sec

Interrupts/Sec is the average rate, in incidents per second, at which the processor received and serviced hardware interrupts. This value is an indirect indicator of the activity of devices that generate interrupts, such as the system clock, the mouse, disk drivers, data communication lines, network interface cards, and other peripheral devices. These devices normally interrupt the processor when they have completed a task or require attention. Normal thread execution is suspended. The system clock typically interrupts the processor every 10 milliseconds, creating a background of interrupt activity. This statistic shows the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Network Output Queue Length/Network Queue Length

The Network Output Queue Length statistic is the number of threads in the processor queue.
Metrics Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than 10 threads per processor is normally acceptable, dependent of the workload.

Correction A sustained high value in the Processor Queue Length could indicate that a processor bottleneck has developed due to threads of a process requiring more process cycles than are available. If this is the case, you should look at installing a faster (or an additional) processor.

Note: The name of this statistic depends on the platform of the operating system.

Page Faults/Sec

The Page Faults/Sec statistic is the overall rate faulted pages are handled by the processor. It is measured in numbers of pages faulted per second. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults and soft faults.

Correction If the number of page faults remains consistently high, you can check with your Windows System Administrator for further investigation. Often, large numbers of page faults are not a problem so long as they are soft faults. However, hard faults, that require disk access, can cause delays.

Processor Queue Length

The Processor Queue Length statistic is the number of threads in the processor queue.
Metrics

Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than 10 threads per processor is normally acceptable, dependent of the workload.

Correction

A sustained high value in the Processor Queue Length could indicate that a processor bottleneck has developed due to threads of a process requiring more process cycles than are available. If this is the case, you should look at installing a faster (or an additional) processor.

Processor Speed

The Processor Speed statistic displays the speed of the active processor in MHz. The speed is approximate.

Processor

The Processor Statistic displays the type of processor currently in use, for example, GenuineIntel.

Memory Analysis Pane

The following metrics are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Available Paged Memory (Windows)
- Available Physical Memory
- Available Swap Memory (AIX, HP-UX, Linux, Solaris, Unix)
- Total Paged Memory/Total Swap Memory
- Total Physical Memory

Tip: To open the Memory tab, right-click any Details menu item.

Note: The statistics available in this section depend on the platform of operating system.
Available Paged Memory

The Available Paged Memory statistic shows the amount of virtual memory available for the processes.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Memory Analysis Pane

Metrics If the available virtual memory is less than 10% of the total virtual memory, your system may run out of memory.

Correction Increase the size of page file.

Note: This statistic is available for the Windows platform.

Available Physical Memory

The Available Physical Memory statistic represents the amount of RAM available to all processes.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Memory Analysis Pane

Metrics This counter displays the last observed value only and not an average. Use this value with the Total physical memory and paging metrics (Memory details page). If the available physical memory is very small compared to this value, and the paging activity is high, your system may be running low on memory.

Correction Some things you can do if you have problems with this statistic include: Check the running processes to see if there are any memory leaks. Stop any services that are not required. Install additional RAM.

Available Swap Memory

The Available Swap Memory statistic represents the amount of virtual memory available for the processes.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Memory Analysis Pane

Metrics If the Available Swap Memory is less than 10% of the total Swap Memory, your system may run out of memory.

Correction Increase the size of swap files.

Total Paged Memory/Total Swap Memory

The Total Paged Memory statistic shows the maximum amount of virtual memory available to all processes.
Metrics  It is recommended that this be 1½ - 3 times the amount of RAM on the system.

Note: The name of this statistic depends on the platform of the operating system.

Total Physical Memory

The Total Physical Memory statistic shows the amount of physical memory installed on your computer.

Metrics  This is an informational metric and displays the total amount installed on the machine. Use this value with the available physical memory and paging metrics (Memory details page). If the available physical memory is very small compared to this value, and the paging activity is high, your system may be running low on memory.

Disk Analysis Pane

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Free Disk Space
- Total Disk Space
- Used Disk Space

Tip: To open the Space tab, right-click any Details menu item.

Note: The statistics available in this section depend on the platform of operating system.

Free Disk Space

The Free Disk Space statistic shows the unallocated space, in megabytes on all logical disk drives.
Correction There are many things a DBA can do to ensure that a database does not encounter a space problem due to physical space limitations:

*If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.*

**Total Disk Space**

Total Disk Space displays the total allocated and unallocated space, in megabytes on all logical disk drives.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Disk Analysis Pane

**Correction** There are many things a DBA can do to ensure that a database does not encounter a space problem due to physical space limitations, here are two:

*If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.*

**Used Disk Space**

The Used Disk Space statistic shows the amount of allocated space, in megabytes on all logical disk drives.

**Location** IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Disk Analysis Pane

**Correction** There are many things a DBA can do to ensure that a database does not encounter a space problem due to physical space limitations:

*If a database currently resides on a disk that has little free space, you can add more files to the database. Of course, you should add the new files to other physical hard disks that can accommodate a growing database. You should examine hard disks with shrinking disk space to see if you can relocate or delete files to allow more free space.*

**Workload Analysis Pane**

The following ratios are used on the Performance Analyst OS home page to succinctly communicate the general overall performance levels of the operating system:

- Number of Logins
Number of Processes

This statistic displays the total number of processes on the server.

Location: IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Disk Analysis Pane

Top CPU Process

Top CPU Process shows the current process that is consuming the most amount of CPU. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location: IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Disk Analysis Pane

Metrics: If the amount of CPU time used by this process is close to 100% and the CPU usage is very high, this process may be the bottleneck on the server.

Correction: Investigate the process further to see if it is in an inconsistent state. Also, look at minimum requirements for CPU speed for the process. You may need to upgrade your CPU.

Top I/O Process

The Top I/O Process statistic shows the current process that is consuming the most amount of CPU. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, and the amount of I/O expressed in KB/sec.

Location: IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Disk Analysis Pane

Metrics: If the amount of CPU time used by this process is close to 100% and the CPU usage is very high, this process may be the bottleneck on the server.

Correction: Investigate the process further to see if it is in an inconsistent state. Also, look at minimum requirements for CPU speed for the process. You may need to upgrade your CPU.

Note: The statistics available in this section depend on the platform of the operating system.
percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Disk Analysis Pane

Top Memory Process

Top Memory Process shows the current process that is consuming the most amount of memory. The information displayed is dependent on the platform of the operating system. Information displayed includes the name of the process, process ID, amount of memory consumed expressed in KB, amount of CPU expressed as a percentage, the amount of Major Page Faults, and the amount of I/O expressed in KB/sec.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Home > Disk Analysis Pane

Metrics  If you are running out of memory on the system, this is a quick way to identify the top memory user. If the displayed process is using a significant portion of the total memory, it could be causing the memory issues.

Processes Overview

The Processes Overview of the OS Summary includes the following sections:

- Top CPU Process
- Top I/O Process
- Top Memory Process

CPU Tab

The CPU tab of the OS Detail includes the following sections:

- Context Switches/Sec
- CPU Events
- CPU Utilization
- Load Averages

The following statistics, available on this tab, are duplicates of statistics on the OS View (DB2 LUW Performance Analyst) Home page:

- Processor Queue Length
- Interrupts/Sec

Note: The sections available on this tab depend on the platform of operating system.
CPU Utilization

The CPU Utilization section includes the following information:

- % Privileged Time
- % User Time

% Privileged Time

The metric shows the percentage of elapsed time that the process threads spent executing code in privileged mode.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > CPU Tab

**Metrics**  
The ideal range should be 0-40% (less than 40% indicates excessive system activity).

**Correction**  
If your CPU consistently runs at less than 40% you may need to upgrade your system to include a faster processor(s).

**Note:** For Windows systems, when a Windows system service is called, the service will often run in privileged mode to gain access to system-private data. Such data is protected from access by threads executing in user mode. Calls to the system can be explicit or implicit, such as page faults or interrupts. These kernel commands, are considered privileged to keep the low-level commands executing and prevent a system freeze. Unlike some early operating systems, Windows uses process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. Some work done by Windows on behalf of the application might appear in other subsystem processes in addition to the privileged time in the process.

% User Time

The % User Time statistic is the percentage of elapsed time the processor spends in the user mode. User mode is a restricted processing mode designed for applications, environment subsystems, and integral subsystems. The alternative, privileged mode, is designed for operating system components and allows direct access to hardware and all memory. The operating system switches application threads to privileged mode to access operating system services. This counter displays the average busy time as a percentage of the sample time.

**Location**  
IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > CPU Tab

**Metrics**  
If the Privileged Time is high in conjunction with Physical Disk Reads, consider upgrading the disk I/O subsystem.

CPU Events

The CPU Events section includes the following information:
Context Switches/Sec

The Context Switches/Sec section shows the combined rate at which all processors on the computer are switched from one thread to another. Context switches occur when a running thread voluntarily relinquishes the processor, is preempted by a higher priority ready thread, or switches between user-mode and privileged (kernel) mode to use an Executive or subsystem service.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > CPU Tab

Metrics The ideal range should be between 0-10,000. GA number greater than 10,000 may indicate too many threads contending for resources.

System Calls/Sec

System calls are functions which require the services of the operating system. Usually they involve access to some data that users must not be permitted to corrupt or even change.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > CPU Tab

Correction Try to find a good ratio between the amount of time the operating system runs (fulfilling system calls and doing process scheduling), and the amount of time the application runs. Your goal should be running 60% to 75% of the time in application mode, and 25% to 40% of the time in operating system mode. If you find that the system is spending 50% of its time in each mode, then you should investigate to determine what is wrong.

Load Averages

The Load Average statistic represents the system load averages over the last 1, 5, and 15 minutes.
Location  IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > CPU Tab

Metrics  High load averages usually mean the system is being used heavily and the response time is correspondingly slow.

Processes Tab

The Processes tab of the OS Detail page succinctly communicates the general overall performance levels of processes. The columns available in this table depend on the platform of operating system. The table below describes the information available in the table on this tab:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process</td>
<td>The name of the process.</td>
</tr>
<tr>
<td>User</td>
<td>The user of the process.</td>
</tr>
<tr>
<td>ID</td>
<td>The ID Process is the unique identifier of this process. ID Process numbers are reused, so they only identify a process for the lifetime of that process.</td>
</tr>
<tr>
<td>CPU</td>
<td>The CPU is the percentage of elapsed time that all of process threads used the processor to execution instructions.</td>
</tr>
<tr>
<td>User Mode</td>
<td>The User Mode is the percentage of elapsed time that the process threads spent executing code in user mode.</td>
</tr>
<tr>
<td>Memory WINDOWS</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory ONLY</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory (MB)</td>
<td>Memory is the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and the process can limit its ability to load libraries.</td>
</tr>
<tr>
<td>Memory</td>
<td>Memory is the percentage of the memory used of the total memory.</td>
</tr>
<tr>
<td>Active Memory</td>
<td>Active Memory is the amount of committed virtual memory, in bytes for this process. Active memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive. This counter displays the last observed value only; it is not an average.</td>
</tr>
<tr>
<td>I/O Data</td>
<td>The rate at which the process is reading and writing bytes in I/O operations. This counter counts all I/O activity generated by the process to include file, network and device I/Os.</td>
</tr>
<tr>
<td>Elapsed Time</td>
<td>The total elapsed time, in seconds, that this process has been running.</td>
</tr>
<tr>
<td>Thread Count</td>
<td>The number of threads currently active in this process. An instruction is the basic unit of execution in a processor, and a thread is the object that executes instructions. Every running process has at least one thread.</td>
</tr>
<tr>
<td>Handle Count</td>
<td>The total number of handles currently open by this process. This number is equal to the sum of the handles currently open by each thread in this process.</td>
</tr>
<tr>
<td>Priority</td>
<td>The current base priority of this process. Threads within a process can raise and lower their own base priority relative to the process' base priority.</td>
</tr>
<tr>
<td>Creating Proc ID</td>
<td>The Creating Process ID value is the Process ID of the process that created the process. The creating process may have terminated, so this value may no longer identify a running process.</td>
</tr>
</tbody>
</table>
Page Faults/Sec is the rate at which page faults by the threads executing in this process are occurring. A page fault occurs when a thread refers to a virtual memory page that is not in its working set in main memory. This may not cause the page to be fetched from disk if it is on the standby list and hence already in main memory, or if it is in use by another process with whom the page is shared.

Page File is the current number of kilobytes that this process has used in the paging file(s). Paging files are used to store pages of memory used by the process that are not contained in other files. Paging files are shared by all processes, and the lack of space in paging files can prevent other processes from allocating memory.

Private is the current size, in kilobytes, of memory that this process has allocated that cannot be shared with other processes.

I/O Tab

The I/O tab includes the following sections:

- Average Disk Queue/Total Disk Queue
- Bytes per I/O Operation
- Disk I/O Time
- Disk Transfers/Sec
- I/O Details
- Transfer Rate

Note: The sections available on this tab depend on the platform of operating system.

I/O Details

The table below describes the information available in this section:
## Column Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disk</td>
<td>The disk number assignment.</td>
</tr>
<tr>
<td>Reading (KB/s)</td>
<td>The amount of bytes read from the device.</td>
</tr>
<tr>
<td>Writing (KB/s)</td>
<td>The amount of bytes written to the device.</td>
</tr>
<tr>
<td>Disk Read Time</td>
<td>Disk Read Time is the percentage of elapsed time that the selected disk drive was busy servicing read requests.</td>
</tr>
<tr>
<td>Disk Write Time</td>
<td>Disk Write Time is the percentage of elapsed time that the selected disk drive was busy servicing write requests.</td>
</tr>
<tr>
<td>Disk Time</td>
<td>Disk Time is the percentage of elapsed time that the selected disk was busy servicing requests.</td>
</tr>
<tr>
<td>Avg. Read Queue</td>
<td>Avg. Disk Read Queue Length is the average number of read requests that were queued for the selected disk during the sample interval.</td>
</tr>
<tr>
<td>Avg. Write Queue</td>
<td>Avg. Disk Write Queue Length is the average number of write requests that were queued for the selected disk during the sample interval.</td>
</tr>
<tr>
<td>Disk Reads/Sec</td>
<td>Disk Reads/Sec is the rate of read operations on the disk.</td>
</tr>
<tr>
<td>Disk Writes/Sec</td>
<td>Disk Writes/Sec is the rate of write operations on the disk.</td>
</tr>
</tbody>
</table>

**Note:** The columns available in this table depend on the platform of operating system.

**Location:** IBMD B2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUL Performance Analyst) > I/O Tab

## Transfer Rate

The Transfer Rate section succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading</td>
<td>The average number of bytes transferred from the disk during read operations.</td>
<td>It is measured in number of KBs per second.</td>
</tr>
<tr>
<td>Writing</td>
<td>The average number of bytes transferred to the disk during write operations.</td>
<td>It is measured in number of KBs per second.</td>
</tr>
<tr>
<td>Transferred</td>
<td>The amount of time required to transfer the data between the device’s cache and the actual device media.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.
Bytes per I/O Operation

The Bytes per I/O Operation section of the OS Detail succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading</td>
<td>The average number of bytes transferred from the disk during read operations.</td>
<td>It is measured in number of bytes per second.</td>
</tr>
<tr>
<td>Writing</td>
<td>The average number of bytes transferred to the disk during write operations.</td>
<td>It is measured in number of bytes per second.</td>
</tr>
</tbody>
</table>

Average Disk Queue/Total Disk Queue

The Average Disk Queue section of the OS Detail page succinctly communicates the general overall performance levels of the server’s I/O. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average Read Queue</td>
<td>Average Read Queue Length is the average number of read requests that were queued for a particular disk.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system.</td>
</tr>
<tr>
<td>Average Write Queue</td>
<td>Average Write Queue is the average number of write requests that were queued for a particular disk.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system. Contact your Windows System Administrator for assistance in troubleshooting these problems.</td>
</tr>
<tr>
<td>Average Queue</td>
<td>Average time in ms. to service I/O requests which for disks includes seek, rotational latency and data transfer time.</td>
<td>Sustained loads on any of the disk queue lengths could represent problems within your system. Contact your Unix System Administrator for assistance in troubleshooting these problems.</td>
</tr>
</tbody>
</table>

Note: The statistics available in this section depend on the platform of operating system.
Correction: Contact your Windows System Administrator for assistance in troubleshooting these problems.

**Disk I/O Time**

The Disk I/O Time section of the OS Detail page succinctly communicates the general overall performance levels of the disk’s I/O. The statistics available in this section depend on the platform of operating system. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>% Disk Read Time</td>
<td>% Disk Read Time is the percentage of time during the sample interval that the disk is busy servicing read requests.</td>
<td>Use this in conjunction with the % Disk Write Time to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
<tr>
<td>% Disk Write Time</td>
<td>% Disk Write Time is the percentage of elapsed time that the selected disk drive was busy servicing write requests.</td>
<td>Use this in conjunction with the % Disk Read Time to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
<tr>
<td>% Disk Time</td>
<td>% Disk Time is the percentage of time during the sample interval that the disk is busy servicing requests.</td>
<td>Use this statistic to identify the disks that may be running at capacity and may require upgrades. This metric may also be used to balance the load between under/over utilized disks.</td>
</tr>
</tbody>
</table>

**Disk Transfers/Sec**

The Disk Transfers/Sec section of the OS Detail page succinctly communicates the general overall performance levels of the disk transfers. The table below describes the statistics in this section:

Location: [IBM DB2 (W/U/L) Performance Analyst statistics](#) > OS View (DB2 LUW Performance Analyst) > I/O Tab
<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reads/Sec</td>
<td>The rate of read operations on the disk.</td>
</tr>
<tr>
<td>Writes/Sec</td>
<td>The rate of write operations on the disk.</td>
</tr>
<tr>
<td>Transfers/Sec</td>
<td>The rate of transfer operations per second.</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.

Location [IBM DB2 (W/U/L) Performance Analyst statistics](#) > OS View (DB2 LUW Performance Analyst) > I/O Tab

## Memory Tab

The Memory tab of the OS Detail page includes the following sections:

- **Buffer Size**
- **Cache Efficiency**
- **Cache Size**
- **Memory Available**
- **Paging Activity**
- **Page Replacements**

The following statistic, available on this tab, duplicates a statistic on the OS View (DB2 LUW Performance Analyst) Memory Tab.

- **Page Faults/Sec**

**Note:** The sections available on this tab depend on the platform of operating system.

## Paging Activity

The Paging Activity section includes the following statistics:

- **Blocks Input/Sec**
- **Blocks Output/Sec**
- **Paged In**
- **Paged Out**
- **Pages Input/Sec**
- **Pages Output/Sec**
Note: The statistics available in this section depend on the platform of operating system.

Blocks Input/Sec

The Blocks Input/sec statistic is the number of blocks sent to a block device per second.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Memory Tab

Correction Although it never hurts to have as much physical memory as your system can handle, here are two things you can check within your system to alleviate the memory bottleneck: Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your swap file. Normally, the bigger the initial size of your swap file, the better, in performance terms.

Blocks Output/Sec

The Blocks Output/sec statistic is the number of blocks received from a block device per second.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Memory Tab

Correction Although it never hurts to have as much physical memory as your system can handle, here are two things you can check within your system to alleviate the memory bottleneck: Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your swap file. Normally, the bigger the initial size of your swap file, the better, in performance terms.

Paged In

The number of disk block paged into core from disk which occurs when the server is experiencing a shortage of RAM. Any nonzero value indicates excessive swap activity. In any virtual memory environment, it is not uncommon to see RAM pages moved out to a swap disk. This is a special disk area in UNIX that’s reserved for holding memory pages so that the processor is capable of addressing RAM in excess of its full capability. While page-out of operations are a normal part of any server’s operations, page-in operations indicate that the real amount of available RAM has been exceeded and that additional RAM pages are required on the server.
Correction High values indicate the possible need to increase the amount of RAM on the system.

Paged Out

The number of disk block paged out of core from disk. In any virtual memory environment, it is not uncommon to see RAM pages moved out to a swap disk. This is a special disk area in UNIX that’s reserved for holding memory pages so that the processor is capable of addressing RAM in excess of its full capability. While page-out of operations are a normal part of any server’s operations, page-in operations indicate that the real amount of available RAM has been exceeded and that additional RAM pages are required on the server.

Pages Input/Sec

The Pages Input/Sec statistic is the number of pages read from disk to resolve hard page faults. Hard page faults occur when a process requires code or data that is not in its working set or elsewhere in physical memory, and must be retrieved from disk.

Correction Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Pages Output/Sec

The Pages Output/Sec statistic is the number of pages written to disk to free up space in physical memory. Pages are written back to disk only if they are changed in physical memory. A high rate of pages output might indicate a memory shortage.
Location  IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Memory Tab

Metrics  Windows NT writes more pages back to disk to free up space when low in physical memory. This counter counts numbers of pages, and can be compared to other counts of pages, without conversion. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval.

Correction  Although it never hurts to have as much physical memory as your system can handle, there are some things you can check within your system to alleviate the memory bottleneck. Check to see if you have any drivers or protocols that are running but not being used. They use space in all memory pools even if they are idle. Check to see if you have additional space on your disk drive that you could use to expand the size of your page file. Normally, the bigger the initial size of your page file, the better, in performance terms.

Memory Available

The Memory Available section of the OS Detail page succinctly communicates the general overall performance levels of the server’s memory. The statistics available in this section depend on the platform of operating system. The table below describes these statistics.
<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Metrics/Correction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical Memory</td>
<td>The Physical Memory statistic is the amount of committed virtual memory, in megabytes. Committed memory is where memory space has been reserved in the paging file if it needs to be written to disk.</td>
<td>This counter displays the last observed value only and not an average.</td>
</tr>
<tr>
<td>Physical</td>
<td>The Physical statistic is the total physical memory available.</td>
<td>N/A</td>
</tr>
<tr>
<td>Paged Memory</td>
<td>The Paged Memory statistic is the amount of committed virtual memory, in bytes. Used Memory is the physical memory which has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive.</td>
<td>This counter displays the last observed value only; it is not an average.</td>
</tr>
<tr>
<td>Swap Memory</td>
<td>The Swap Memory statistic is the free, unreserved swap space.</td>
<td>Increase the size of your swap file or add additional files if you consistently see a shortage of free, unreserved swap space.</td>
</tr>
<tr>
<td>Swap</td>
<td>The Swap statistic is the total swap memory being used.</td>
<td>N/A</td>
</tr>
<tr>
<td>Total Physical</td>
<td>The Total Physical statistic is the total physical memory available.</td>
<td>N/A</td>
</tr>
<tr>
<td>Total Swap</td>
<td>The Total Swap statistic is the total swap memory available.</td>
<td>N/A</td>
</tr>
<tr>
<td>Swap-ins</td>
<td>The number of memory pages paged in from swapspace.</td>
<td>If the system is consistently low on free memory (over a 30 second average), the memory scheduler will start to swap out processes. Increase the size of your swap file or add additional files.</td>
</tr>
<tr>
<td>Swap-outs</td>
<td>The number of memory pages paged in from swapspace.</td>
<td>If the system is consistently low on free memory (over a 30 second average), the memory scheduler will start to swap out processes. Increase the size of your swap file or add additional files.</td>
</tr>
<tr>
<td>Buffers</td>
<td>The Buffers statistic represents the amount of buffers used by the kernel in kilobytes.</td>
<td>N/A</td>
</tr>
</tbody>
</table>
Page Faults/Sec

The Page Faults/Sec statistic is the overall rate faulted pages are handled by the processor. It is measured in numbers of pages faulted per second. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults and soft faults. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval. If the number of page faults remains consistently high, you can check with your Windows System Administrator for further investigation. Often, large numbers of page faults are not a problem so long as they are soft faults. However, hard faults, that require disk access, can cause delays.

Buffer Size

The Buffer Size statistic represents the amount of cache used by the kernel in kilobytes.

Cache Size

The Cache Size statistic represents the amount of cache used by the kernel in kilobytes.

Page Replacements

The following statistics are available in this section:

- Memory Freed (Pages/sec)
- Clock Algorithm Scans (Pages/sec)

Memory Freed (Pages/sec)

Freed or destroyed (Kb/s).

Clock Algorithm Scans (Pages/sec)

The VMM uses a technique known as the clock algorithm to select pages to be replaced. This technique takes advantage of a referenced bit for each page as an indication of what pages have been recently used (referenced). When the page-stealer routine is called, it cycles through the PFT, examining each page's referenced bit.
Cache Efficiency

The Cache Efficiency section of the Memory tab succinctly communicates the general overall performance levels of the server's memory. The following statistics are available in this section:

- **Copy Read Hits %**
- **Data Map Hits %**
- **MDL Read Hits %**
- **Pin Read Hits %**

**Copy Read Hits %**

The Copy Read Hits % statistic is the percentage of cache copy read requests that hit the cache and does not require a disk read to provide access to the page in the cache.

**Metrics**

When the page is pinned in the memory, the page's physical address in the file system cache will not be altered. A copy read is a file read operation where a page in the cache is copied to the application's buffer. Because this value reflects hits, it ideally should be close to 100%. An amount below 100% indicates misses.

**Correction**

Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

**Data Map Hits %**

The Data Map Hits % statistic is the percentage of data maps in the file system cache that could be resolved without having to retrieve a page from the disk.
MDL Read Hits %

The MDL Read Hits % statistic is the percentage of Memory Descriptor List Read requests to the file system cache that hit the cache and does not require disk access to provide memory access to the pages in the cache.

Correction Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

Pin Read Hits %

The Pin Read Hits % statistic is the percentage of pin read requests that hit the file system cache and does not require a disk read in order to provide access to the page in the file system cache.

Correction Adding physical memory to a server results in a larger file system cache, which is generally more efficient. Defragmenting disks also helps, putting related pages in the cache together and thereby improving the cache hit rate.

Space Tab

The Space tab of the OS Detail page includes the following sections:

- Device Summary
- Device Detail
Disk Space Free

The Disk Space Free metric displays the amount of free disk space in megabytes.

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Space Tab

Disk Space Detail

The Disk Space Detail section of the Space tab succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition</td>
<td>The drive letter of the disk.</td>
</tr>
<tr>
<td>Local Filesystem</td>
<td>The name of the file system.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of file system.</td>
</tr>
<tr>
<td>Total Space</td>
<td>Total size of the disk/device's capacity expressed in MBs.</td>
</tr>
<tr>
<td>Used Space</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free Space</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
<tr>
<td>Capacity</td>
<td>The percentage of space used on the device.</td>
</tr>
<tr>
<td>Mounted On</td>
<td>The mount point of the device.</td>
</tr>
</tbody>
</table>

Location IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Space Tab

Device Summary

The Device Summary section of the Space tab displays a bar chart for all devices. The Device Summary section succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Used</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
</tbody>
</table>
Device Detail

The Device Detail section of the Space tab succinctly communicates the general overall performance levels of the server’s disks and space allotment. The table below describes the statistics in this section:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition</td>
<td>The drive letter of the disk.</td>
</tr>
<tr>
<td>Local Filesystem</td>
<td>The name of the file system.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of file system.</td>
</tr>
<tr>
<td>Total Space</td>
<td>Total size of the disk/device's capacity expressed in MBs.</td>
</tr>
<tr>
<td>Used Space</td>
<td>Amount of MBs currently allocated on the particular disk/device.</td>
</tr>
<tr>
<td>Free Space</td>
<td>Amount of MBs currently unallocated and free on the particular disk/device.</td>
</tr>
<tr>
<td>Capacity</td>
<td>The percentage of space used on the device.</td>
</tr>
<tr>
<td>Mounted On</td>
<td>The mount point of the device.</td>
</tr>
</tbody>
</table>

**Note:** The statistics available in this section depend on the platform of operating system.

Network Tab

The Network tab of the OS Detail page succinctly communicates the general overall performance levels of the server’s networking. The Network tab of the OS Detail page includes the following sections:

- Network Details
- Packet Collisions
- Packet Discards
- Packet Errors
- Transmission Rate
- Transmission Rate (Bytes)
- Transmission Queue Length
**Note:** The sections available on this tab depend on the platform of operating system.

## Network Details

The statistics available in this section depend on the platform of operating system. The table below describes the information available in this section:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network Interface</td>
<td>The name of network interface.</td>
</tr>
<tr>
<td>INET Address/Address</td>
<td>The IP address assigned to the network interface.</td>
</tr>
<tr>
<td>Pkts Sent/Sec</td>
<td>The number of packets sent per second.</td>
</tr>
<tr>
<td>Pkts Received/Sec</td>
<td>The number of packets received per second.</td>
</tr>
<tr>
<td>Sent (KB/Sec)</td>
<td>The number of bytes sent per second.</td>
</tr>
<tr>
<td>Received (KB/Sec)</td>
<td>The number of bytes received per second.</td>
</tr>
<tr>
<td>Out Pkts Discarded</td>
<td>The number of outbound packets discarded.</td>
</tr>
<tr>
<td>In Pkts Discarded</td>
<td>The number of inbound packets discarded.</td>
</tr>
<tr>
<td>Out Pkt Errors</td>
<td>The number of outbound packet errors.</td>
</tr>
<tr>
<td>In Pkt Errors</td>
<td>The number of inbound packet errors.</td>
</tr>
<tr>
<td>Queue Length</td>
<td>The queue length.</td>
</tr>
<tr>
<td>Collisions</td>
<td>The number of collisions.</td>
</tr>
<tr>
<td>Packets Discarded</td>
<td>The number of packets discarded.</td>
</tr>
</tbody>
</table>

**Location**  
[IBM DB2 (W/U/L) Performance Analyst statistics] > OS View (DB2 LUW Performance Analyst) > Network Tab

## Transmission Rate

The Transmission Rate section of the Network tab succinctly communicates the packet transmission rate. The following statistics are available in this section:

<table>
<thead>
<tr>
<th>Packets Sent/Sec</th>
<th>The Packets Sent/Sec statistic is the number of packets sent over each network adapter per second.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Packets Received/Sec</td>
<td>The Packets Received/Sec statistic is the number of packets received over each network adapter per second.</td>
</tr>
</tbody>
</table>
Transmission Rate (Bytes)

The Transmission Rate (Bytes) section of the Network tab succinctly communicates the packet transmission rate. The following statistics are available in this section:

- **Sent (KB/Sec)**
  
  The Sent (KB/Sec) statistic is the rate at which bytes are sent over each network adapter including framing characters.

- **Received (KB/Sec)**
  
  The Received (KB/Sec) statistic is the rate at which bytes are received over each network adapter, including framing characters.

Transmission Queue Length

The number of pending outgoing packets on either the software transmit queue or the hardware transmit queue.

Packet Collisions

A collision occurs when two devices on the network sense that the network is idle and end up trying to send data at the same time. Some collisions are normal on a repeated network, but excess collisions can cause serious performance problems.

Correction

Contact your network administrator if there is high rate of persistent Packet Collisions.

Packet Discards

The Packet Discards section of the Network tab succinctly communicates the packet discard rate. The following statistics are available in this section:
Outbound Packets Discarded

The Outbound Packets Discarded statistic is the number of outbound packets that were discarded even though no errors had been detected to prevent from being transmitted.

Inbound Packets Discarded

Received Packets Discarded is the number of received packets that were discarded even though no errors had been detected to prevent from being transmitted.

Packet Discards

The Packet Discards statistic represents the number of network packets discarded.

Location

IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Space Tab

Correction

A possible reason for discarding such a packet could be to free up buffer space. Contact your network administrator if there is high rate of persistent packet discards.

Packet Errors

The Packet Errors section of the Network tab succinctly communicates the packet error rate. The following statistics are available in this section:

Outbound Packet Errors

The Outbound Packet Errors statistic is the outbound packets that contained errors preventing them from being deliverable to a higher-layer protocol.

Inbound Packet Errors

The Packets Received Errors statistic is the received packets that contained errors preventing them from being deliverable to a higher-layer protocol.

Location

IBM DB2 (W/U/L) Performance Analyst statistics > OS View (DB2 LUW Performance Analyst) > Space Tab
Top SQL View (DB2 LUW Performance Analyst)

One or two bad queries can cause a lot of trouble for the remaining sessions in a database, and so can one or two bad queries. It is important to find them before they get into a production system, but sometimes a few sneak through.

By applying custom filters and performance-related thresholds, the Top SQL view locates inefficient SQL. By applying filters to certain I/O and statistical counters, you hope to isolate queries that far exceed their nearest competitors in the same area (like disk reads). When you find them, you should reduce the number of sorts a query performs. Or, for a query that returns only a few records, you should try to minimize the number of rows a query processes.

Metrics

When you begin to look for inefficient SQL in a database, there are two primary questions you need to answer:

- What has been the worst SQL that’s historically been run in my database?
- What is the worst SQL that’s running right now in my database?

When troubleshooting a slow system, you should be on the lookout for any query that shows an execution count that is significantly larger than any other query on the system. It may be that the query is in an inefficient loop, or other problematic programming construct. Only by bringing the query to the attention of the application developers will you know if the query is being mishandled from a programming standpoint.

The following tabs are available on the Top SQL page:

- Summary tab
- Criteria tab
- SQL Details tab
- Dynamic SQL Cache tab

Summary tab

The Summary tab is divided into two sections:

- Top SQL Statements
- Top SQL Details
Top SQL Statements

A lot of a database’s overall performance can be attributed to SQL statement execution. Poorly optimized SQL statements or stored procedures can drag an otherwise well-configured database down in terms of user response times.

Before you can identify problem SQL in your database, you have to ask the question of what ‘bad SQL’ is. What criteria do you use when you begin the hunt for problem SQL in your critical systems? Understand that even the seasoned experts disagree on what constitutes efficient and inefficient SQL; so there is no way to sufficiently answer this question to every SQL Server professional’s satisfaction. The Top SQL results grid displays the top SQL statements across various performance categories including Reads, Writes, CPU statistics, and Elapsed Time.

Top SQL Details

This section shows the details of the top SQL statements. The columns presented here include:

- **Usage**: % of all operations of this type performed by the selected SQL statement.
- **SQL text**: Text of the selected SQL statement.
- **Total Reads**: Total number of read operations performed by the selected SQL statement.
- **Total Writes**: Total number of write operations performed by the selected SQL statement.
- **Executions**: Number of times the selected SQL statement was executed.
- **First Start Time**: First time the selected SQL statement was executed.
- **Avg CPU Time**: Avg CPU time used by the selected SQL statement.
- **Avg Elapsed Time**: Avg Elapsed time for selected SQL statement.

Criteria tab

The Top SQL view displays all SQL running or executed in the current datasource. You can use the lists and boxes to reorder the display according to your specific needs. The Criteria tab of the Top SQL page includes the following sections that you can mix and match to give you the information you want to find.

- **Demographic Criteria**
- **Statistical Criteria**
- **Sort Criteria**
SQL Details tab

The SQL Details tab presents the following sections:

- Top SQL Results
- Selected SQL Text
- Selected SQL Last Snapshot Details

Top SQL Results

This section shows the details of the SQL statements and (their metrics) captured at each refresh of the performance analyst. The information presented here includes:

- SQL text: Partial text of the captured SQL statement. The full text is shown in the selected SQL text section.
- Agents Top: The maximum number of agents that were used when executing the selected statement at the time of last refresh
- Max Agents Top: the maximum number of agents that were used when executing the selected statement over all captured executions
- Fetch Count: Number of successful fetches performed for the specific statement at the time of last refresh
- Avg Fetch Count: Avg number of successful fetches for the selected statement over all its captured executions
- Int. Rows Deleted: Number of internal rows deleted for the selected statement as a result of internal activity
- Avg Int Rows Deleted: over all its captured executions
- Int Rows Inserted
- Avg Int Rows Inserted over all its captured executions
- Int. Rows Updated
- Avg Internal Rows Updated over all its captured executions
  1. Agents
  2. Rows Estimate
- Avg # Rows Estimate over all its captured executions
- Cost Estimate
- Avg Cost Estimate over all its captured executions
- Rows Read
Top SQL View (DB2 LUW Performance Analyst)

- Avg Rows Read over all its captured executions
- Rows Written
- Avg Rows Written over all its captured executions
- Sorts
- Avg Sorts over all its captured executions
- Sys CPU Time
- Avg Sys CPU Time over all its captured executions
- Usr CPU Time
- Avg Usr CPU Time over all its captured executions
- Total Sort Time
- Avg Total Sort Time over all its captured executions
- Buffer pool Hit Ratio
- Overall Buffer pool Hit Ratio over all its captured executions
- Temp Data Hit Ratio
- Overall Temp Data Hit Ratio over all its captured executions

**Selected SQL Text**

The Selected SQL Text window allows you to select any of the Top SQL result rows and get the complete SQL text. From here you can open an Explain Plan or Tune the SQL.

**Selected SQL Last Snapshot Details**

This displays attributes for the last snapshot of the selected SQL statement

**Dynamic SQL Cache tab**

The Dynamic SQL Cache tab of the Top SQL view, displays the following sections:

- Dynamic SQL Cache Details
- Dynamic SQL Statement
- Execution and Preparation Details
- Bufferpool Analysis
- Execution Time Details
Dynamic SQL Cache Details

The DB2 statement cache stores packages and statistics for frequently used SQL statements. This section shows the statements in this cache and the metrics associated with each statement.

Metrics

By examining the contents of this cache, you can identify the dynamic SQL statements that are most frequently executed and the queries that consume the most resources. Using this information, you can examine the most commonly executed and most expensive SQL operations, to determine if SQL tuning could result in better database performance.

Dynamic SQL Statement

The Dynamic SQL Text window allows you to select any of the Dynamic SQL Cache Detail and get the complete SQL text. From here you can open an Explain Plan or Tune the SQL.

Execution and Preparation Details

Here you see the number of times the selected SQL statement was compiled and executed.

Metrics

You can use the execution information to identify the most commonly executed SQL statements in your system. You will probably see the greatest performance benefit from tuning them.

You can use the compilation information to determine the number of different compilations for the selected SQL statement. Use this information together with the number of executions to determine if a bad compilation environment is skewing the metrics.

Bufferpool Analysis

This section shows the various bufferpool usage metrics for the selected SQL statement.

Metrics

This information helps you determine the scope when you tune bufferpools.

Execution Time Details

The information presented here may be used to identify the longest running SQL.

Metrics
The longest running SQL statements together with the most frequently used SQL statements help you identify the most likely candidates for SQL tuning.

**Space Analyst**

Space management plays a key role in a database’s uptime and overall performance. Because of this, it’s important that a database administrator understand the various types of space bottlenecks that can occur in a database.

Embarcadero Space Analyst provides sophisticated diagnostic capabilities to help you effectively locate and troubleshoot bottlenecks and performance inefficiencies that result from the challenges of space management. Running inside the Embarcadero DBArtisan console, Space Analyst automates all diagnostic and correction procedures so any space-related headache can be quickly detected and corrected before it reaches critical mass.

The table below describes the major sections of the help available for the Space Analyst.

<table>
<thead>
<tr>

Welcome to Space Analyst

Space Analyst provides sophisticated diagnostic capabilities to troubleshoot bottlenecks and performance problems that result from poor space management. Space Analyst helps ensure that database storage is being used as efficiently as possible.

Space Analyst also includes a Reorganization Wizard as part of the Space Management Wizard that handles full storage structure and object reorganization needs.

Licensing Space Analyst

Availability of this feature depends on your licensing. For more information, see Licensing.

- What You Should Know Before Installing Space Analyst
- Opening an Analyst
- Uninstalling a Repository
What You Should Know Before Installing Space Analyst

When you install the Analyst, several Embarcadero-generated stored objects are pushed onto the database server.

These objects are as follows:

**SQL Server**

Procedures

- `sp_embt_sa_database_map`
- `sp_embt_sa_database_overview`
- `sp_embt_sa_dbbottlenecks`
- `sp_embt_sa_filegroups`
- `sp_embt_sa_files`
- `sp_embt_sa_index_space_general`
- `sp_embt_sa_index_space_reorg`
- `sp_embt_sa_index_space_reorg_summary`
- `sp_embt_sa_table_space_general`
- `sp_embt_sa_table_space_reorg`
- `sp_embt_sa_table_space_reorg_summary`
- `sp_embt_sa_index_reorg_summary`
- `sp_embt_sa_table_reorg_summary`
- `sp_embt_sa_version`

**Sybase ASE**

Procedures

- `sp_embt_sa_dbspace`
- `sp_embt_sa_device_summary`
- `sp_embt_sa_device_detail`
- `sp_embt_sa_database_overview`
- `sp_embt.sa_db.obj_space`
- `sp_embt.sa_database_detail`
- `sp_embt.sa_db frag_summary`
- `sp_embt.sa_index_diag_summary`
- `sp_embt.sa_index_diag`
- `sp_embt.sa_server_overview`
- `sp_embt.sa_table_diag_summary`
- `sp_embt.sa_table_diag`
- `sp_embt.sa_version`

**Note:** No procedures are installed in Space Analyst for Oracle or DB2.
Opening an Analyst

To open the Space Analyst, do the following:

1. On the Analyst menu, click Space Analyst.

**Note:** The first time that you open the Space Analyst, DBArtisan alerts you that you need to install the Analyst’s procedures. If you elect to install the procedures, an **Analyst Repository Installation** dialog opens, prompting for credentials and other security details. When you install the Analyst, several procedures and tables are pushed onto the database server. For a list of these procedures and tables, see [What You Should Know Before Installing Space Analyst](#).

Uninstalling a Repository

To uninstall an Analyst repository, do the following:

1. On the Command menu, select Uninstall Repository.

The Analyst Repository Uninstallation Wizard opens.

**Analyst Repository Uninstallation Wizard - Panel 1**

The table below describes the options and functionality on this panel of the Analyst Repository Uninstallation Wizard:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Administrator Login Information</td>
<td>Displays the login name, password, and login as information.</td>
</tr>
<tr>
<td>Database to hold the procedures</td>
<td>Displays the database that stores the procedures.</td>
</tr>
<tr>
<td>Uninstall</td>
<td>Uninstalls the repository and opens Panel 2. For more information, see <a href="#">Analyst Repository Uninstallation Wizard - Panel 2</a>.</td>
</tr>
</tbody>
</table>

**Analyst Repository Uninstallation Wizard - Panel 2**

The table below describes the options and functionality on this panel of the Analyst Repository Uninstallation Wizard:
Space Analyst Application Basics

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository Login</td>
<td>Displays repository login.</td>
</tr>
<tr>
<td>Execution Log</td>
<td>Displays the repository execution log and links to ETRepoLog.txt.</td>
</tr>
<tr>
<td>Execution Error(s)</td>
<td>Displays any errors.</td>
</tr>
<tr>
<td>Finish</td>
<td>Closes wizard.</td>
</tr>
</tbody>
</table>

**Space Analyst Application Basics**

The Space Analyst utility assists DBAs with space diagnostics and reorganizations by displaying pertinent reorganization diagnostics and providing a Reorganization Wizard as part of the [Space Management Wizard](#) that builds scripts that you can execute or schedule to perform reorganizations.

**Topics**

- [Product Design](#)
Space Analyst Product Design

The Space Analyst product design includes tabs for Oracle, Microsoft SQL Server and IBM DB2.

Oracle Space Analyst Tabs

The Space Analyst includes the following tabs:

- Database Overview Tab
- Datafiles Tab
- Tablespace Map Tab
- Tables Tab
- Indexes Tab

Microsoft SQL Server Space Analyst Tabs

The Space Analyst includes the following tabs:

- Storage Overview Tab
- Files/File Groups Tab
- Map Tab
- Databases Tab
- Objects Tab

IBM DB2 Space Analyst Tabs

The Space Analyst includes the following tabs:

- Database Overview Tab
- Tablespaces Tab
- Tablespace Map Tab
- Tables Tab
- Indexes Tab

Sybase ASE Space Analyst Tabs

The Space Analyst includes the following tabs:

- Storage Overview Tab
Database Overview Tab

The **Database Overview** tab displays the storage overview for the DB2 datasource. There are four distinct sections displayed on the first **Database Overview** tab of Space Analyst:

- Database Overview
- Log Overview (DB2 Only)
- Tablespace Space Overview
- Tablespace Fragmentation Overview
- Tablespace Objects Overview

Data Files Tab

The **Data Files** tab displays datafile fragmentation information, and displays how much space in each datafile is assigned to tables, indexes, clusters, and rollback segments.

Tablespace Map Tab

The **Tablespace Map** tab allows for tablespace mapping.

Tables Tab

The **Tables** tab lets you identify tables with wasted space. The Space Analyst computes a block inefficiency ratio that quickly communicates the severity of the space problem. Space Analyst provides a summary count of all tables in a database that violate a customizable block inefficiency threshold, details on the tables, and the extent of wasted space.

Indexes Tab

The **Indexes** tab lets you select index reorganization candidates. The tab also offers the option to obtain deleted leaf row information for each index, although such data gathering can take some time, especially on large systems.

Space Analyst runs diagnostics against your database and graphically display a count of indexes that are found to contain various types of space problems.
Tables Tab

The *Tables Tab* displays the Tablespace Container allocations and Database Partition Breakdown for each Tablespace.

There are three distinct sections displayed on the *Tablesspaces* tab of Space Analyst:

- Space Allocation by Container
- Space Allocation by Node
- Tablespaces

Using Space Analyst

Using Space Analyst covers how to use each component of the application. The Using chapter breaks each process and procedure into simple step-by-step instructions.

The Space Analyst includes the following tabs, by platform:

**Space Analyst for Oracle**

- [Database Overview Tab](#)
- [Datafiles Tab](#)
- [Tablespace Map Tab](#)
- [Tables Tab](#)
- [Indexes Tab](#)

**Space Analyst for Microsoft SQL Server**

- [Storage Overview Tab](#)
- [Files/File Groups Tab](#)

Space Analyst for Oracle and IBM DB2 for Linux, Unix, and Windows - Database Overview Tab

The Database Overview tab lets you view the global storage picture of your database.

The table below describes the options and functionality on the Database Overview tab of Space Analyst for Oracle:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Overview</td>
<td>Shows how much space in KB is taken up in the database by various object types (tables, indexes, etc.) along with a pie chart that represents the percentage of each object type. You can switch between the default graphical view and a grid view. NOTE: Objects owned by SYS and SYSTEM are not included in this breakdown.</td>
</tr>
<tr>
<td>Tablespace Space Overview</td>
<td>When in graphical mode, this section contains a bar chart graph that displays all tablespaces and how much total space each has allocated. When in grid mode, Space Analyst displays detailed information about all tablespaces (status, total, used, free, percent free, etc.) ORACLE ONLY: When in grid mode, Space Analyst displays tablespace status. You can switch between the default graphical view and a grid view.</td>
</tr>
<tr>
<td>Tablespace Fragmentation Overview</td>
<td>Contains fragmentation information for all tablespaces and displays how badly fragmented a tablespace or datafile is. Higher scores for the tablespace’s fragmentation index indicate little or no fragmentation, while lower scores indicate fragmentation. You can switch between graphical and grid views of tablespace fragmentation. If fragmentation is present, you can view detailed object and fragmentation information for the tablespace in the tablesnapce map. You can correct fragmentation problems via Space Analyst’s Reorganization Wizard. You can switch between the default graphical view and a grid view.</td>
</tr>
<tr>
<td>Tablespace Objects Overview</td>
<td>Contains a grid that displays how much space in each tablespace is assigned to tables, indexes, clusters, and rollback segments. ORACLE ONLY: When in grid mode, Space Analyst displays tablespace LOB data values.</td>
</tr>
</tbody>
</table>

The table below describes the options and functionality on the Database Overview tab of Space Analyst for IBM DB2 for Linux, Unix, and Windows:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Overview</td>
<td>Shows how much space in KB is taken up in the database by various object types (tables, indexes, etc.) along with a pie chart that represents the percentage of each object type. You can switch between the default graphical view and a grid view.</td>
</tr>
<tr>
<td>Log Space Overview</td>
<td>Displays all of the log options for the database: Total Used Total Free Block Log When Disk Full Log File Size User Exit Primary Logs Secondary Logs Maximum Secondary Log Space Used Maximum Total Log Space Used</td>
</tr>
<tr>
<td>Tablespace Space Overview</td>
<td>When in graphical mode, this section contains a bar chart graph that displays all tablespaces and how much total space each has allocated. When in grid mode, displays detailed information about all tablespaces: Name Type State Used Space (MB) Free Space (MB) Content Type (Any, Long, Temp, System temp) Number of containers NOTE: You can switch between the default graphical view and a grid view.</td>
</tr>
<tr>
<td>Tablespace Objects Overview</td>
<td>Contains a grid that displays how much space in each tablespace is assigned to each object. Also displays tablespace LOB data values. Displays detailed information about all tablespace objects: Tablespace Name Table - total space used by tables Index - total space used by indexes Extent Size - tablespace extent size Page size - Tablespace page size</td>
</tr>
</tbody>
</table>

**Available Functionality**

The following functionality is available in the Command menu, shortcut menu, and toolbar:

**Note:** Functionality differ by platform.

- Analysis Report
- Convert to Dictionary-Managed
- Convert to Locally-Managed
- Extract
- Estimate Size
- Map
- Open Editor. For information on modifying database objects, see [Modifying objects using editors](#).
  - Open Wizard
  - Reorganize
  - Update Statistics
  - Tablespaces Wizard (DB2 LUW)
  - Threshold Options
Space Analyst for Oracle and IBM DB2 for Linux, Unix, and Windows - Datafiles Tab

The **Data Files** tab lets you view fragmentation and object placement information for data files.

The table below describes the options and functionality on the **Datafiles** tab of the Space Analyst:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datafile Fragmentation</td>
<td>Displays fragmentation about datafiles. Higher scores for a datafile’s fragmentation index indicate little or no fragmentation, while lower scores indicate fragmentation. If fragmentation is present, you can view detailed object and fragmentation information for the datafile’s tablespace in the tablespace map. You can correct fragmentation problems via Space Analyst’s Reorganization Wizard. NOTE: Datafiles for temporary tablespaces are not included in the Datafile Fragmentation grid.</td>
</tr>
<tr>
<td>Datafile Objects Overview</td>
<td>Contains a grid that displays how much space in each datafile is assigned to tables, indexes, clusters, and rollback segments.</td>
</tr>
</tbody>
</table>

**Tip:** To open a Tablespace Editor, right-click a datafile in any grid, and then select Open. To extract the tablespace DDL in an ISQL editor, right-click a datafile in any grid, and then select Extract.

**Available Functionality**

The following functionality is available in the Command menu, shortcut menu, and toolbar:

**Note:** Functionalists differ by platform.

- **Analysis Report**
- **Convert to Dictionary-Managed**
- **Convert to Locally-Managed**
- **Estimate Size**
- **Extract**
- **Map**

**Open Editor.** For information on modifying database objects, see [Modifying objects using editors](#).

- **Reorganize**
Space Analyst for Oracle - Tablespace Map Tab

○ Threshold Options

Topics
○ Space Analyst Tabs.

Space Analyst for Oracle - Tablespace Map Tab

The Tablespace Map tab lets you view a graphical layout regarding the physical placement of every object inside a selected tablespace. The tablespace map also helps identify fragmentation problems for a tablespace (honeycomb and bubble). An object grid is also present that lets you view detailed information about every object's storage properties.

The Space Info section contains information regarding the total, used, and free space (in MB) for the tablespace.

The View By section allows you to switch between two different tablespace map views:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Type</td>
<td>The normal tablespace map mode, which is color-coded by object type. Pressing the legend button shows the various colors assigned to the object types contained within the tablespace.</td>
</tr>
<tr>
<td>Extent Problems</td>
<td>When in this mode, the tablespace map highlights in red any object containing one or both of these object extent problems: - Max extent problem - the object has reached or is near its maximum extent limit. - Extent deficit - the object may not be able to allocate its next extent because the tablespace does not currently have enough contiguous free space. This problem will be highlighted even if the tablespace has its autoextend property for one or more datafiles set to true.</td>
</tr>
</tbody>
</table>

When in Object Type mode, the accompanying grid of the tablespace map contains the following data:
Space Analyst for Oracle - Tablespace Map Tab

<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the object in owner.object name.partition name format.</td>
</tr>
<tr>
<td>Extents</td>
<td>The total number of allocated extents for the object.</td>
</tr>
<tr>
<td>Blocks</td>
<td>The total number of allocated blocks for the object.</td>
</tr>
<tr>
<td>Bytes</td>
<td>The total number of allocated bytes for the object.</td>
</tr>
<tr>
<td>Type</td>
<td>The object type (table, index, etc.)</td>
</tr>
<tr>
<td>Initial Extent</td>
<td>The initial space extent (in bytes) allocated to the object.</td>
</tr>
<tr>
<td>Next Extent</td>
<td>The next extent (in bytes) that the object will attempt to allocate when more</td>
</tr>
<tr>
<td></td>
<td>space for the object is required.</td>
</tr>
<tr>
<td>Percent</td>
<td>The percent increase property for the object.</td>
</tr>
<tr>
<td>Increase</td>
<td></td>
</tr>
</tbody>
</table>

When in Extent Problems mode, the accompanying grid of the tablespace map contains the following data:

<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the object in owner.object name.partition name format.</td>
</tr>
<tr>
<td>Extents</td>
<td>The total number of allocated extents for the object.</td>
</tr>
<tr>
<td>Blocks</td>
<td>The total number of allocated blocks for the object.</td>
</tr>
<tr>
<td>Bytes</td>
<td>The total number of allocated bytes for the object.</td>
</tr>
<tr>
<td>Type</td>
<td>The object type (table, index, etc.)</td>
</tr>
<tr>
<td>Initial Extent</td>
<td>The initial space extent (in bytes) allocated to the object.</td>
</tr>
<tr>
<td>Next Extent</td>
<td>The next extent (in bytes) that the object will attempt to allocate when more</td>
</tr>
<tr>
<td></td>
<td>space for the object is required.</td>
</tr>
<tr>
<td>Percent</td>
<td>The percent increase property for the object.</td>
</tr>
<tr>
<td>Increase</td>
<td></td>
</tr>
<tr>
<td>Max Extent</td>
<td>A percentage indicating how close the object is to reaching its maximum extent</td>
</tr>
<tr>
<td>Percent</td>
<td>limit. For example, a 100 indicates an object that has reached its maximum</td>
</tr>
<tr>
<td></td>
<td>extent limit.</td>
</tr>
<tr>
<td>Extendibility</td>
<td>Indicates if the object can allocate its next extent. If 'N', this is because</td>
</tr>
<tr>
<td></td>
<td>the tablespace does not currently have enough contiguous free space. This problem</td>
</tr>
<tr>
<td></td>
<td>will be highlighted even if the tablespace has its autoextend property for one or</td>
</tr>
<tr>
<td></td>
<td>more datafiles set to true.</td>
</tr>
</tbody>
</table>

When viewing a tablespace in the graphical map, there are two broad categories of fragmentation that you will want to be on the lookout for: free space honeycombs and
free space bubbles. Honeycomb fragmentation is really not difficult to detect or handle and occurs when two free space extents in a tablespace reside next to one another. For example, rather than having one large free space extent of 6MB, a tablespace might have two extents that are next to each other (a honeycomb) that make up 3MB and 3MB. If an incoming object required a single 4MB extent allocation, Oracle would have to coalesce the honeycomb to make room for the object. The necessary coalesce operation would cause a small degree of performance degradation, however the situation would be resolved and no space-related bottleneck would remain.

Fragmentation bubbles, however, are another story and are the traditional reason DBAs have had to perform full tablespace reorganizations. Bubbles occur when objects are continuously added and dropped in a tablespace, with the end result being free space pockets (or bubbles) being interspersed between objects that remain in the tablespace. This can become problematic when, for example, an incoming object requires a single 5MB extent allocation, but there is not enough contiguous space in the tablespace to meet the demand. Even if the total amount of free space in the tablespace equals the required 5MB, it will do no good if that 5MB is made up of 5 non-contiguous blocks of free space. In this situation, Oracle has no alternative but to either extend the datafile to make room for the object (if the tablespace's datafile has the AUTOEXTEND property enabled), or return an error and deny the object entry into the tablespace.

Space Analyst makes it easy to recognize both of these bottleneck headaches. When the map is viewed in Object Type mode, pockets of green seen throughout the tablespace indicate bubble fragmentation, while two or more blocks of green segments viewed next to one another in the map indicate honeycomb fragmentation.

The Tablespace Map tab includes the following buttons:

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Legend</td>
<td>Opens the Tablespace Map Legend.</td>
</tr>
<tr>
<td>Display</td>
<td>Opens the Display window. The Display window lets you specifies the magnification level for the Tablespace Map.</td>
</tr>
<tr>
<td>Fit to Window</td>
<td>Fits the Tablespace Map to the window.</td>
</tr>
<tr>
<td>Full Screen</td>
<td>Fits the Tablespace Map to the full screen.</td>
</tr>
<tr>
<td>Print Map</td>
<td>Opens the Print dialog to print the Tablespace Map.</td>
</tr>
</tbody>
</table>

Topics

- Space Analyst Tabs
Space Analyst for Oracle, Sybase ASE, and IBM DB2 for Linux, Unix, and Windows - Tables Tab

The Tables tab displays diagnostic information regarding table space inefficiencies that may exist in your database.

The Table Reorganization Candidate Summary section uses a bar chart to count the various types of table space inefficiencies in your database. Note that the reorganization threshold options are used to compute the counts for each type of space inefficiency.

The table below describes the four distinct types of table space inefficiencies that Space Analyst computes for Oracle and Sybase ASE:

<table>
<thead>
<tr>
<th>Problem</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Inefficiencies</td>
<td>These tables have wasted space that exceeds the allowable percentage of wasted space set in the customizable thresholds of Space Analyst (to see all the thresholds, click the toolbar option labeled Reorganization Threshold Options). Tables with wasted space can take longer to scan and therefore contribute to slower response times.</td>
</tr>
<tr>
<td>Next Extent Problems</td>
<td>These tables cannot obtain their next extent of free space due to a lack of needed contiguous free space in the tablespace. Tables suffering from this problem may produce error conditions in the database if more data is added to them. This problem will be highlighted even if the tablespace that contains the table has its autoextend property for one or more datafiles set to true.</td>
</tr>
<tr>
<td>Chain Problems</td>
<td>These tables suffer from a chained or migrated row problem. The percentage of chained or migrated rows to overall rows contained in the table exceeds the allowable percentage of chained rows set in the customizable thresholds of Space Analyst (to see all the thresholds, click the toolbar option labeled Reorganization Threshold Options). Because chained/migrated rows cause more I/O to occur when they are accessed, overall response times can be degraded when these tables are referenced in SQL queries.</td>
</tr>
<tr>
<td>Max Extent Problems</td>
<td>These tables are nearing their maximum extent limit and have exceeded the allowable maximum extent percentage set in the customizable thresholds of Space Analyst (to see all the thresholds, click the toolbar option labeled Reorganization Threshold Options). Tables suffering from this problem may cause space-related errors to result if more data is added to them.</td>
</tr>
</tbody>
</table>

The Table Reorganization Candidate Details section provides filters and a grid that you can use to view detailed space diagnostics for all or selected tables. The table below describes the grid data:
<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Owner</td>
<td>The owner of the table.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>Segment Type</td>
<td>Indicates if the object is a table, table partition, etc.</td>
</tr>
<tr>
<td>Table (KB)</td>
<td>The total allocated space of the table in KB.</td>
</tr>
<tr>
<td>Number of Rows</td>
<td>The number of rows that the table contains. NOTE: This column may report NULL if the table has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Number of Blocks</td>
<td>The total number of blocks allocated to the table. NOTE: This column may report NULL if the table has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Empty Blocks</td>
<td>The number of empty blocks that the table contains. NOTE: This column may report NULL if the table has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Highwater Mark</td>
<td>The last block that Oracle will scan up to when searching the table for data. NOTE: This column may report NULL if the table has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Average Used Blocks</td>
<td>The average number of blocks that the table is using. NOTE: This column may report NULL if the table has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Block Inefficiency</td>
<td>A percentage that indicates how much wasted space (space that the table is not using) that the table contains. High percentages indicate tables that may be candidates for reorganization. NOTE: This column may report NULL if the table has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Chained Row Percent</td>
<td>A percentage that indicates how many rows in the table suffer from chaining or migration. High percentages indicate tables that may be candidates for reorganization. NOTE: This column may report NULL if the table has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Max Extent Percent</td>
<td>A percentage indicating how close an object is to reaching its maximum extent limit. High percentages indicate tables that may be candidates for reorganization.</td>
</tr>
<tr>
<td>Number of Extents</td>
<td>The number of extents that the table consumes.</td>
</tr>
<tr>
<td>Max Extents</td>
<td>The maximum extent limit for the table.</td>
</tr>
<tr>
<td>Extent Deficit</td>
<td>Indicates if the object can allocate its next extent. If 'N', this is because the tablespace does not currently have enough contiguous free space. This problem will be highlighted even if the tablespace has its autoextend property for one or more datafiles set to true.</td>
</tr>
</tbody>
</table>
Next Extent  The next extent (in bytes) that the table will attempt to allocate when more space for the table is required.

Max Free Space  The largest contiguous block of free space that exists in the tablespace where the table resides.

Tablespace Name  The tablespace that contains the table.

IBM DB2 for Linux, Unix, and Windows

The table below describes the four distinct types of Reorganization Candidate Summary that Space Analyst computes for IBM DB2 for Linux, Unix, and Windows:

<table>
<thead>
<tr>
<th>Problem</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overflow Problems</td>
<td>Displays the number of tables that fall outside the preset limits for the thresholds of this area. Can be addressed with reorganization of the affected table(s).</td>
</tr>
<tr>
<td>Space Utilization Problem</td>
<td>Displays the number of tables that fall outside the preset limits for the thresholds of this area. Can be addressed with reorganization of the affected table(s).</td>
</tr>
<tr>
<td>Page Utilization Problem</td>
<td>Displays the number of tables that fall outside the preset limits for the thresholds of this area. Can be addressed with reorganization of the affected table(s).</td>
</tr>
<tr>
<td>Index Contention</td>
<td>Displays the number of tables where the index space is shared by the Tablespace. To resolve, use the <a href="#">Space Management Wizard</a> to change the Index Tablespace in table definition.</td>
</tr>
</tbody>
</table>

The table below describes the options and functionality on the Table Reorganization Candidate Details section:

The Table Reorganization Candidate Details section provides filters and a grid that you can use to view detailed space diagnostics for all or selected tables. The table below describes the grid data:
### Data Description

<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Schema</td>
<td>The schema name for the table.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>Cardinality</td>
<td>The number of rows in the table.</td>
</tr>
<tr>
<td>Size</td>
<td>The size of Table in bytes.</td>
</tr>
<tr>
<td>Overflow</td>
<td>The number of overflow rows. Overflow rows can be created when rows are</td>
</tr>
<tr>
<td></td>
<td>updated and the new rows contain more bytes than the old ones (VARCHAR fields), or when columns are added to existing tables.</td>
</tr>
<tr>
<td>Pages with Data</td>
<td>The number of allocated pages that contain data.</td>
</tr>
<tr>
<td>Total Pages</td>
<td>The total number of allocated pages.</td>
</tr>
<tr>
<td>Active Blocks</td>
<td>The number of Active Blocks in Tables with Multidimensional clustering.</td>
</tr>
<tr>
<td>Overflow %</td>
<td>Percentage of overflow rows. This should typical be a small value (5%).</td>
</tr>
<tr>
<td>Space Utilization%</td>
<td>A low space utilization is an indicator of excessive fragmentation (internal and external). This can occur when there are many pages with free space and/or many free pages. This should typically be &gt; 68%.</td>
</tr>
<tr>
<td>Page Utilization %</td>
<td>A low page utilization is an indicator of excessive external fragmentation. This value should typically be more than 80%.</td>
</tr>
<tr>
<td>Reorg</td>
<td>This is an indicator of how severe the fragmentation problem for the table is. --- means Overflow%, Space Utilization% and Page Utilization % are all with in the thresholds. <em>-</em> means that Overflow%, and Page Utilization % are outside the threshold but Space Utilization% is with in the threshold.</td>
</tr>
<tr>
<td>Tablespace</td>
<td>Tablespace where the table data resides.</td>
</tr>
<tr>
<td>Indexspace</td>
<td>Tablespace where the index data resides.</td>
</tr>

Space Analyst for Oracle - Tables Tab

The Tables tab displays diagnostic information regarding table space inefficiencies that may exist in your database.

The Table Reorganization Candidate Summary section uses a bar chart to count the various types of table space inefficiencies in your database. Note that the reorganization threshold options are used to compute the counts for each type of space inefficiency.

The table below describes the four distinct types of table space inefficiencies that Space Analyst computes for Oracle and Sybase ASE:

<table>
<thead>
<tr>
<th>Problem</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Inefficiencies</td>
<td>These tables have wasted space that exceeds the allowable percentage of wasted space set in the customizable thresholds of Space Analyst (to see all the thresholds, click the toolbar option labeled Reorganization Threshold Options). Tables with wasted space can take longer to scan and therefore contribute to slower response times.</td>
</tr>
<tr>
<td>Next Extent Problems</td>
<td>These tables cannot obtain their next extent of free space due to a lack of needed contiguous free space in the tablespace. Tables suffering from this problem may produce error conditions in the database if more data is added to them. This problem will be highlighted even if the tablespace that contains the table has its autoextend property for one or more datafiles set to true.</td>
</tr>
<tr>
<td>Chain Problems</td>
<td>These tables suffer from a chained or migrated row problem. The percentage of chained or migrated rows to overall rows contained in the table exceeds the allowable percentage of chained rows set in the customizable thresholds of Space Analyst (to see all the thresholds, click the toolbar option labeled Reorganization Threshold Options). Because chained/migrated rows cause more I/O to occur when they are accessed, overall response times can be degraded when these tables are referenced in SQL queries.</td>
</tr>
<tr>
<td>Max Extent Problems</td>
<td>These tables are nearing their maximum extent limit and have exceeded the allowable maximum extent percentage set in the customizable thresholds of Space Analyst (to see all the thresholds, click the toolbar option labeled Reorganization Threshold Options). Tables suffering from this problem may cause space-related errors to result if more data is added to them.</td>
</tr>
</tbody>
</table>

The Table Reorganization Candidate Details section provides filters and a grid that you can use to view detailed space diagnostics for all or selected tables. The table below describes the grid data:
### Data

<table>
<thead>
<tr>
<th>Description</th>

<td>Indicates if the object can allocate its next extent. If 'N', this is because the tablespace does not currently have enough contiguous free space. This problem will be highlighted even if the tablespace has its autoextend property for one or more datafiles set to true.</td>
</tr>
</tbody>
</table>
Next Extent: The next extent (in bytes) that the table will attempt to allocate when more space for the table is required.

Max Free Space: The largest contiguous block of free space that exists in the tablespace where the table resides.

Tablespace Name: The tablespace that contains the table.

**IBM DB2 for Linux, Unix, and Windows**

The table below describes the four distinct types of Reorganization Candidate Summary that Space Analyst computes for IBM DB2 for Linux, Unix, and Windows:

<table>
<thead>
<tr>
<th>Problem</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overflow Problems</td>
<td>Displays the number of tables that fall outside the preset limits for the thresholds of this area. Can be addressed with reorganization of the affected table(s).</td>
</tr>
<tr>
<td>Space Utilization Problem</td>
<td>Displays the number of tables that fall outside the preset limits for the thresholds of this area. Can be addressed with reorganization of the affected table(s).</td>
</tr>
<tr>
<td>Page Utilization Problem</td>
<td>Displays the number of tables that fall outside the preset limits for the thresholds of this area. Can be addressed with reorganization of the affected table(s).</td>
</tr>
<tr>
<td>Index Contention</td>
<td>Displays the number of tables where the index space is shared by the Tablespace. To resolve, use the Space Management Wizard to change the Index Tablespace in table definition.</td>
</tr>
</tbody>
</table>

The table below describes the options and functionality on the Table Reorganization Candidate Details section:
Option | Description
---|---
Tablespace | Displays all Tablespaces (regular) in the database and the value [All].
Table Schema | Displays all schema in the database and the value [All].
Display | All Tables with Overflow Problems - Displays a list of all tables where overflow threshold is exceeded. Tables with Space Utilization problems - Displays a list of all tables where space utilization threshold is exceeded. Tables with Page Utilization problems - Displays a list of all tables where the page utilization threshold is exceeded. Tables with Index Contention - Displays a list of all tables where the table and indexes on the table share the same Tablespace.
Refresh | Refreshes the table grid with criteria selected in the above lists.

The Table Reorganization Candidate Details section provides filters and a grid that you can use to view detailed space diagnostics for all or selected tables. The table below describes the grid data:
<table>
<thead>

Space Analyst for Sybase ASE and IBM DB2 for Linux, Unix, and Windows - Indexes Tab

The Indexes tab displays diagnostic information regarding index space inefficiencies that may exist in your database.

The Index Reorganization Candidate Summary section uses a bar chart to count the various types of index space inefficiencies in your database. Note that the reorganization threshold options are used to compute the counts for each type of space inefficiency.

The table below describes the three distinct types of table space inefficiencies that Space Analyst computes:

<table>
<thead>
<tr>
<th>Problem</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLevel</td>
<td>These indexes have extended beyond the allowable B-level size set in the customizable thresholds of Space Analyst (to see all the thresholds, click the toolbar option labeled Reorganization Threshold Options). Indexes with extended levels can take longer to scan and can therefore contribute to slower response times.</td>
</tr>
<tr>
<td>Next Extent</td>
<td>These indexes cannot obtain their next extent of free space due to a lack of needed contiguous free space in the tablespace. Indexes suffering from this problem may cause space-related errors if more data is added to their parent table. This problem will be highlighted even if the tablespace that contains the table has its autoextend property for one or more datafiles set to true.</td>
</tr>
<tr>
<td>Max Extent</td>
<td>These indexes are nearing their maximum extent limit and have exceeded the allowable maximum extent percentage set in the customizable thresholds of Space Analyst (to see all the thresholds, click the toolbar option labeled Reorganization Threshold Options). Indexes suffering from this problem may cause space-related errors to result if more data is added to their parent table.</td>
</tr>
</tbody>
</table>

The Index Reorganization Candidate Details section provides filters and a grid that you can use to view detailed space diagnostics for all or selected indexes. The grid contains the following data:
<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index Owner</td>
<td>The owner of the index.</td>
</tr>
<tr>
<td>Index Name</td>
<td>The name of the index.</td>
</tr>
<tr>
<td>Index Type</td>
<td>Indicates if the type of index (index, index partition, etc.)</td>
</tr>
<tr>
<td>Index (KB)</td>
<td>The total allocated space of the index in KB.</td>
</tr>
<tr>
<td>Number of Rows</td>
<td>The number of rows that the parent table contains. <strong>Note:</strong> This column may report NULL if the table has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Clustering Factor</td>
<td>Indicates the amount of order of the rows in the table based on the values of the index. If the value is near the number of blocks, then the table is very well ordered. If the value is near the number of rows, then the table is very randomly ordered. In this case, it is unlikely that index entries in the same leaf block point to rows in the same data blocks.</td>
</tr>
<tr>
<td>Index Blevel</td>
<td>Indicates the level of the index. Numbers beyond 3-4 can indicate a fragmented index.</td>
</tr>
<tr>
<td>Number of Blocks</td>
<td>The total number of blocks allocated to the index. <strong>Note:</strong> this column may report NULL if the index has not been analyzed via the ANALYZE command or through the DBMS_STATS package.</td>
</tr>
<tr>
<td>Max Extent Percent</td>
<td>A percentage indicating how close an object is to reaching its maximum extent limit. High percentages indicate indexes that may be candidates for reorganization.</td>
</tr>
<tr>
<td>Number of Extents</td>
<td>The number of extents that the index consumes.</td>
</tr>
<tr>
<td>Max Extents</td>
<td>The maximum extent limit for the index.</td>
</tr>
<tr>
<td>Can Extent Space</td>
<td>Indicates if the object can allocate its next extent. If 'N', this is because the tablespace does not currently have enough contiguous free space. This problem will be highlighted even if the tablespace has its autoextend property for one or more datafiles set to true.</td>
</tr>
<tr>
<td>Next Extent</td>
<td>The next extent (in bytes) that the index will attempt to allocate when more space for the index is required.</td>
</tr>
<tr>
<td>Max Free Space</td>
<td>The largest contiguous block of free space that exists in the tablespace where the index resides.</td>
</tr>
<tr>
<td>Tablespace Name</td>
<td>The tablespace that contains the index.</td>
</tr>
</tbody>
</table>

**Note:** The grid can also contain a column for deleted leaf rows if the Get Deleted Leaf Row Statistics option has been selected. Be aware that the calculation of this statistic can
take a lot of time for databases with large numbers of indexes. Large numbers of deleted leaf rows can indicate an index in need of reorganization.

**IBM DB2 for Linux, Unix, and Windows**

The Index Reorganization Candidate Summary section uses a bar chart to represent the various types of index space inefficiencies in your database:

- Indexes with Cluster Ratio Problems
- Indexes with Used Space% problems
- Indexes with Balance Problems
- Indexes with Deleted RID problems
- Indexes with Empty Leaf Problems
- Indexes with Low Uniqueness

**Note:** Space Analyst uses the options you select in the Reorganization Wizard to compute each type of space inefficiency.

**Tip:** All of the problems in the Index Reorganization Candidate Summary section except low cardinality can be corrected with index reorganization. The Low cardinality is an indicator of an index where the columns on which it is defined have low level of uniqueness. Such indexes should either be dropped or changed to include columns that will make the index more unique.

The table below describes the options and functionality on the Index Reorganization Candidate Details section:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace</td>
<td>Displays all Tablespaces (regular/large) in the database and the value [All].</td>
</tr>
<tr>
<td>Index Schema</td>
<td>Displays all schema in the database and the value [All].</td>
</tr>
<tr>
<td>Display</td>
<td>All Indexes Indexes with Cluster Ratio Problems Indexes with Used Space% problems Indexes with Balance Problems Indexes with Deleted RID problems Indexes with Empty Leaf Problems Indexes with Low Uniqueness</td>
</tr>
<tr>
<td>Refresh</td>
<td>Refreshes the index grid with criteria selected in the above lists.</td>
</tr>
</tbody>
</table>

The Index Reorganization Candidate Details section provides filters and a grid that you can use to view detailed space diagnostics for all or selected indexes. The grid contains the following data:
<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index Schema</td>
<td>The schema name for the index.</td>
</tr>
<tr>
<td>Index Name</td>
<td>The name of the index.</td>
</tr>
<tr>
<td>Table Schema</td>
<td>The schema name for the base table</td>
</tr>
<tr>
<td>Table Name</td>
<td>The base table name.</td>
</tr>
<tr>
<td>Table Cardinility</td>
<td>The number of rows in the base table.</td>
</tr>
<tr>
<td>Avg Key Size</td>
<td>The index key size, calculated from the average column length of all columns participating in the index.</td>
</tr>
<tr>
<td>Leafs</td>
<td>The total number of index leaf pages.</td>
</tr>
<tr>
<td>Pseudo Empty Leafs</td>
<td>The number of pseudo empty index leaf pages. A pseudo empty index leaf page is a page on which all the RIDs are marked as deleted, but have not been physically removed.</td>
</tr>
<tr>
<td>Pseudo Deleted RIDs</td>
<td>A RID that is marked deleted. This statistic reports pseudo deletes RIDs on leaf pages that are not pseudo empty. It does not include RIDs marked as deleted on leaf pages where all the RIDs are marked deleted.</td>
</tr>
<tr>
<td>Levels</td>
<td>The number of index levels.</td>
</tr>
<tr>
<td>Unique Entries</td>
<td>The number of unique index entries that are not marked deleted.</td>
</tr>
<tr>
<td>Page Size</td>
<td>The page size of the table space in which the table indexes reside, specified at the time of table creation.</td>
</tr>
<tr>
<td>% Free</td>
<td>Specifies the percentage of each index page to leave as free space, a value that is assigned when defining the index.</td>
</tr>
<tr>
<td>Cluster Ratio</td>
<td>The clustering ratio of an index should be greater than 80 percent. When multiple indexes are defined on one table, some of these indexes have a low cluster ratio. (The index sequence is not the same as the table sequence.) This cannot be avoided. Be sure to specify the most important index when reorganizing the table. The cluster ratio is usually not optimal for indexes that contain many duplicate keys and many entries.</td>
</tr>
<tr>
<td>Used Space%</td>
<td>Less than 50 percent of the space reserved for index entries should be empty.</td>
</tr>
</tbody>
</table>
Space Analyst for Sybase ASE and IBM DB2 for Linux, Unix, and Windows - Indexes Tab

Balance  To determine if recreating the index would result in a tree having fewer levels. This formula checks the ratio between the amount of space in an index tree that has one less level than the current tree, and the amount of space needed. If a tree with one less level could be created and still leave PCTFREE available, then a reorganization is recommended. The actual number of index entries should be more than 90% (or 100-PCTFREE) of the number of entries an NLEVELS-1 index tree can handle (only checked if NLEVELS>1).

Deleted RIDs  The number of pseudo-deleted RIDs on non-pseudo-empty pages should be less than 20 percent.

Empty Leaf  The number of pseudo-empty leaf pages should be less than 20 percent of the total number of leaf pages.

Uniqueness  100 * Index Cardinality / Table Cardinality - A low index uniqueness may indicate the need to Alter or Drop the index.

Reorg  An indicator of how severe the fragmentation problem for the index is. Each hyphen (-) displayed in this column indicates that the calculated results were within the set bounds of the corresponding formula, and each asterisk (*) indicates that the calculated result exceeded the set bounds of its corresponding formula: - or * on the left column corresponds to Cluster Ratio - or * in the second from left column corresponds to Used Space% - or * in the middle column corresponds to Balance - or * in the second column from the right corresponds to Deleted RIDs - or * on the right column corresponds to Empty Leaf

Tablespace  The tablespace where the table data resides.

Indexspace  The tablespace where the index data resides.

Space Analyst - Storage Overview Tab

The **Storage Overview** tab displays an overview of the storage/space situation on the target server:

The table below describes the sections on the **Storage Overview** tab of Space Analyst for Microsoft:

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server Overview</td>
<td>Overview of total database and log space allocated on the SQL Server, as well as a count of databases, files, and file groups.</td>
</tr>
<tr>
<td>Log Overview</td>
<td>Contains a graphical and grid control that works in the following way: - When the graph is displayed, a bar chart is shown that lists the total percent used of all logs on the server. - When the grid is displayed, detailed storage information for each database log is presented.</td>
</tr>
<tr>
<td>Database Overview</td>
<td>Contains a graphical and grid control that works in the following way: - When the graph is displayed, a bar chart is shown that lists the total space usage of all databases on the server. - When the grid is displayed, detailed storage information for each database is presented.</td>
</tr>
<tr>
<td>Server Disk Overview</td>
<td>Contains an overview of total free space, by physical server drive, of the server that houses SQL Server.</td>
</tr>
</tbody>
</table>

The table below describes the sections on the **Storage Overview** tab of Space Analyst for Sybase ASE:

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server Overview</td>
<td>Overview of total database and log space allocated on the Sybase ASE Server, as well as a count of databases and devices.</td>
</tr>
<tr>
<td>Log Overview</td>
<td>Contains a graphical and grid control that works in the following way: - When the graph is displayed, a bar chart is shown that lists the total percent used of all logs on the server. - When the grid is displayed, detailed storage information for each database log is presented: Database name Total log space Free log space Used log space Log percent free</td>
</tr>
<tr>
<td>Database Overview</td>
<td>Contains a graphical and grid control that works in the following way: - When the graph is displayed, a bar chart is shown that lists the total space usage of all databases on the server. - When the grid is displayed, detailed storage information for each database is presented: Database name Total database space Database free space Database used space Database percent free</td>
</tr>
<tr>
<td>Device Overview</td>
<td>Contains a graphical and grid control that works in the following way: - When the graph is displayed, a bar chart is shown that lists the total space used (in MB) of all devices defined to the server. - When the grid is displayed, detailed storage information for each database device is presented: Device name Physical name Total space Used space Free space Percent free Percent used</td>
</tr>
</tbody>
</table>

**Available Functionality**
The following functionality is available in the Command menu, shortcut menu, and toolbar for Microsoft:

- Analysis Report
- Extract
- Map
- Databases Wizard (SQL Server)
- Object Details
- Open Editor
- Open Wizard
- DBCC
- Shrink
- Threshold Options

**Available Functionality**

The following functionality is available in the Command menu, shortcut menu, and toolbar for Sybase ASE:

- Pinpointing 'out of space' Problems
- Space Analyst Tabs
Space Analyst for Microsoft - File Groups/Files Tab

The **Files/File Groups** tab displays a graph and grid for filegroups on the server and a grid for files.

**Tip:** You can toggle between the graphs and grid views.

The **File Groups/Files** tab reports space usage on SQL Server by file group and by file.

When the File Groups radio button is pressed, Space Analyst presents a graphical layout of file group space usage across all databases. For large servers, not all file groups will initially be shown, but the graph is scrollable so you can click the graph and scroll to see all file groups on the chart. When in grid mode, more detailed information is shown for each file group including its auto-growth properties, how many files make up the group, the amounts (in MB) taken up by tables and indexes, and more.

When the Files radio button is pressed, detailed information is displayed for each individual file for every database on the server.

**Available Functionality**

The following functionality is available in the Command menu, shortcut menu, and toolbar:

- Analysis Report
- Extract
- Map
- Databases Wizard (SQL Server)

- Space Analyst Tabs
Space Analyst for Microsoft - Map Tab

The Map tab displays a graphical file map that displays extent placement for objects within database files.

The Map tab lets you view a graphical layout regarding the physical placement of every object inside a selected database and file. The map helps identify allocated and unused extents throughout a database file. An object grid is also present that lets you view detailed information about every object’s storage usage in that file. Keep in mind that an object can span more than one file.

The Space Info section at the top contains information regarding the total number of extents allocated to a database file, a count of extents that contain table data, a count of extents that contain index data, and a count of extents that contain text data.

Databases are comprised of logical pages, each of which is a fixed 8KB in size. Note that the 8KB page is also a unit of I/O, which affects performance and locking. Extents are collections of database pages. An extent is made up of eight, 8K pages and is therefore 64KB in size. Extents are the graphical “blocks” displayed in the map.

Extents come in two flavors - uniform and mixed. Uniform extents ascribe all eight database pages to a single object, whereas mixed extents have the potential to hold multiple objects. With mixed extents, SQL Server tries to preserve space by not letting very small objects take up an entire extent and therefore waste a lot of space. By placing your mouse pointer over an extent “block” in the map, Space Analyst will present a pop-up dialog displaying what object(s) is/are contained in that extent.

The table below describes the options and functionality on the Map tab of Space Analyst:
### Option | Description
---|---
Space Info | Displays total extent count, extents with tables count, extents with indexes count, and extents with text count. Note that an extent can contain more than one object and more than one object type.

Map | Displays object extent data from beginning to end of the database or file. All blocks in the map are the same size. A Microsoft SQL Server extent is 64KB in size or 8, 8K pages. Purple - Indicate extents that have been allocated to objects (used), and extents that are free. Green - Free extents.

Owner | Displays table owner.

Table name | Displays table name.

Object type | Displays object type.

Index name | Displays index name.

Pages used | Displays pages used.

Pages allocated | Displays pages allocated.

In extents | How many extents each object is in.

Table id | Displays table id.

Index id | Displays index id.

### The Tablespace Map tab includes the following buttons:

| Button | Description |
---|---|
Legend | Opens the Tablespace Map Legend. |
Display | Opens the Display window. The Display window lets you specifies the magnification level for the Tablespace Map. |
Fit to Window | Fits the Tablespace Map to the window. |
Full Screen | Fits the Tablespace Map to the full screen. |
Print Map | Opens the Print dialog to print the Tablespace Map. |

### Available Functionality

The following functionality is available in the Command menu, shortcut menu, and toolbar:
Topics

- **Analysis Report**

- **Object Details**
- **Open Editor**
- **Open Wizard**
- **DBCC**
- **Shrink**
- **Threshold Options**

**Space Analyst Tabs**
Space Analyst for Microsoft - Databases Tab

The **Databases** tab lets you analyze databases.

**Tip:** You can toggle between the graphs and grid views.

The **Databases** tab displays information regarding space usage across all databases, potential space-related bottlenecks that are threatening databases, and recent database backup information.

When in graph form, the Database Summary section displays a graphical view of table, index, and free space usage (in MB) across all databases. For large servers, not all databases will initially be shown, but the graph is scrollable so you can click the graph and scroll to see all databases on the chart. When in grid form, the Database Summary section displays much more detail regarding database and log usage, object counts, and more.

The Database Bottlenecks section provides a graphical count of various space-related bottlenecks that are threatening the availability of your databases (some of which are controlled by Space Analyst’s customizable thresholds). When in grid form, each database is listed along with information that relays whether or not a potential bottleneck exists for that database.

The Database Backups section details the most recent backup for each database and the size (in MB) of the backup.

**Available Functionality**

The following functionality is available in the Command menu, shortcut menu, and toolbar:

- Analysis Report
- Extract
- Map
- Databases Wizard (SQL Server)
- Object Details
- Open Editor
- Open Wizard
- DBCC
- Shrink
- Threshold Options
Space Analyst for Microsoft - Objects Tab

The **Objects** tab displays database objects, including tables and indexes.

You can choose whether to view table or index information by clicking either the Tables or Indexes ratio buttons. You can also choose whether to view general space information for tables and indexes or reorganization metrics by selecting the General Space or Space Diagnostics radio buttons.

**Note:** To obtain space diagnostic information for each object, Space Analyst uses the SQL Server DBCC SHOWCONTIG command. This command may take a while to run on large databases.

The Object summary presents one of two views:

- When the General Space radio button is pressed, a graph is presented that visually displays that amount of allocated space (in KB) for tables, indexes, and free space. For large servers, not all objects for a database will initially be visible on the chart, but the graph is scrollable so you can click the graph and scroll to see all database objects on the chart.

- When the Space Diagnostics radio button is pressed, Space Analyst presents a count of all objects (tables or indexes) that exceed your customizable thresholds for various forms of fragmentation of other space-related inefficiency. See below for a thorough discussion of these types of space problems.

The Object Details grid presents one of two views:

- When the General Space radio button is pressed, general space usage for tables or indexes is shown. Base object metadata (object name, type, partitions, etc.) is shown along with the amounts of total, used, and free space (in KB) for the object. The percent of space used for the object is also shown along with the percent of space in the database that the object consumes.

- When the Space Diagnostics radio button is pressed, Space Analyst present fragmentation and other space-related inefficiency information for all objects in the selected database. Note that definitions for all the various forms of object fragmentation and space inefficiencies follow later in the help.

The table below describes the options and functionality on the **Objects** tab of Space Analyst:
Space Analyst for Microsoft - Objects Tab

<table>
<thead>
<tr>

Space Analyst - Analysis Report

The Analysis Report dialog lets you build an HTML analysis report for the selected tablespace. You can run reports on a recurring basis and dynamically alter any saved thresholds that flag space problems in the tablespace being analyzed.

For Oracle, the report includes sections for particular reorganization needs, including:

- Fragmentation index for the tablespace
- Tables with high block inefficiencies
- Tables or indexes with next extent space deficit problems
- Tables or indexes with maximum extent limit problems
- Tables or indexes with percent increase greater than zero
- Tables with chained/migrated row problems
- Indexes with B-tree depth problems

For Microsoft, the report contains different sections that highlight particular reorganization needs, including:

- Free space levels for the database and log
- Tables with forwarded record problems
- Indexes with average fragmentation problems
- Tables or indexes with extent fragmentation problems
- Tables or indexes with logical fragmentation problems
- Tables or indexes with scan density problems
- Tables or indexes with average page density problems

For Sybase ASE, the report contains different sections that highlight particular reorganization needs, including:

- Free space levels for the database and log
- Tables with forwarded row problems
- Tables with empty page problems
- Tables with deleted row problems
Space Analyst Functionality

- Tables with low fragmentation scores
- Indexes with unused space problems
- Indexes with empty leaf problems
- Indexes with height/level problems
- Indexes with low fragmentation scores

For IBM DB2 for Linux, Unix, and Windows, the report contains different sections that highlight particular reorganization needs, including:

- Tables with overflow problems
- Tables with space utilization problems
- Tables with page utilization problems
- Tables with index space contention
- Indexes with cluster ratio problems
- Indexes with used space% problems
- Indexes with balance problems
- Indexes with deleted RID problems
- Indexes with empty leaf problems
- Indexes with low uniqueness
- Free levels of tablespace and log space

**To open the Analysis Report dialog box:**

1. Open the Space Analyst.
2. On the Command menu, click the Analysis Report.

For all platforms, browse to or type a report title and make your desired selections from the drop-down lists. After the report executes, you can print it or save it.

**To print the report:**

1. Click Print from the Analysis Report toolbar.

**To save the report:**

1. Select Save from the File menu on the main toolbar.
Space Analyst - Convert to Locally-managed

The Convert to Locally-Managed dialog lets you convert a dictionary-managed tablespace to locally-managed. Objects in locally-managed tablespaces have unlimited extents; they will never fail to extend due to an imposed maximum extent limit.

Important Notes

There are a few restrictions on these conversion procedures (for example, Oracle9i UNDO tablespaces currently can’t be converted, etc.), so you should check the Oracle documentation for the specifics on performing a conversion.

The Convert to Locally-Managed option is only available if the selected tablespace(s) are:

- ONLINE
- In Read/Write mode
- Dictionary managed
- Not UNDO tablespaces
- Not Temporary tablespaces
- Not the SYSTEM tablespace

The table below describes the options and functionality on the Convert to Locally-Managed dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespaces to be Converted</td>
<td>Displays the tablespaces to be converted to locally-managed.</td>
</tr>
<tr>
<td>Conversion Options</td>
<td>OPTIONAL: Lets you type allocation unit and relative file number information.</td>
</tr>
</tbody>
</table>

Completing the Convert to Locally-Managed Dialog Box for Space Analyst

To complete this dialog box, do the following:

1. Select Convert to Locally-Managed.

OR

2. Right-click the target object, and then select Convert to Locally-Managed.

The Space Analyst opens the dialog box.

3. Do one of the following:
Space Analyst Functionality

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Preview" /></td>
<td>Opens the Preview dialog.</td>
</tr>
<tr>
<td><img src="image" alt="Schedule" /></td>
<td>Opens a scheduling application.</td>
</tr>
<tr>
<td><img src="image" alt="Execute" /></td>
<td>Executes the task.</td>
</tr>
</tbody>
</table>

### Space Analyst - Convert to Dictionary-Managed

**Note:** The Convert to Dictionary-Managed functionality is for Oracle 9i only.

The Convert to Dictionary-Managed dialog lets you convert a locally-managed tablespace to dictionary.

**Important Notes**

The Convert to Dictionary-Managed dialog is only available if the selected tablespace(s) are:

- ONLINE
- In Read/Write mode
- Locally managed
- Not UNDO tablespaces
- Not Temporary tablespaces
- Not the SYSTEM tablespace

The table below describes the options and functionality on the Convert to Dictionary-Managed dialog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespaces to be Converted</td>
<td>Displays the tablespaces to be converted to dictionary-managed.</td>
</tr>
</tbody>
</table>

**Completing the Dictionary-Managed Dialog Box for Space Analyst**

To complete this dialog box, do the following:

1. Select Convert to Dictionary-Managed.

OR

2. Right-click the target object, and then select Convert to Dictionary-Managed.

The Space Analyst opens the dialog box.
3. Do one of the following:

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Preview" /></td>
<td>Opens the Preview dialog.</td>
</tr>
<tr>
<td><img src="image" alt="Schedule" /></td>
<td>Opens a scheduling application.</td>
</tr>
<tr>
<td><img src="image" alt="Execute" /></td>
<td>Executes the task.</td>
</tr>
</tbody>
</table>

**Space Analyst - Extract**

The Extract functionality lets you extract the database DDL in an ISQL editor.

To extract the database DDL in an ISQL editor, do the following:

1. Click the Extract DDL button.

**OR**

2. Select Extract.

**OR**

3. Right-click the target object, and then select Extract.

Space Analyst extract the database DDL in an ISQL editor.

**Space Analyst - Map**

The Map functionality opens the Tablespace Map tab or Map tab of the Space Analyst for the selected index.

**Important Notes**

None

**Opening the Tablespace Map Tab for Space Analyst**

To open the Tablespace Map or Map tab, do the following:

1. Select Map.

**OR**

2. Right-click the target object, and then select Map.

Space Analyst open the Tablespace Map tab or Map tab.
Space Analyst - Open Editor

The Open functionality lets you modify objects in the object editors.

To open the object editor, do the following:

1. In any grid, select an object.
2. Click the Open Editor button.

OR

3. Select Open.

OR

4. Right-click the target object, and then select Open.

Space Analyst opens the object editor.
Space Management Wizard

The Space Management Wizard can create two specialized space management jobs that allow you to proactively eliminate space threats before they affect your database:

Reorganize

You can create a "reorganization analyst job" that allows you to specifically select various databases and/or objects and then set reorganization thresholds that determine when a reorganization will occur. Once constructed, you can schedule these jobs to run as often as you’d like. During execution, these jobs will interrogate your chosen database/objects and determine if a reorganization needs to occur by applying your customized reorganization thresholds. If any objects are found to need reorganization, they are dynamically reorganized using any customized options you specify.

You can build space maintenance jobs that will perform functions such as check the validity of your databases and filegroups, repair any found minor corruption, and eliminate unused space in your databases. You can also set the job up to notify you if any problems are found during job execution.

Creating or editing a space Management Job

The Space Management Wizard lets you create space reorganization or maintenance jobs without knowing the code. After creation, jobs can be reused as is, or edited.

To open the Space Management Wizard

1. Start the Space Analyst and click the Open Wizard button on the Space Analyst toolbar.

OR

2. Select Open Wizard from the Space Analyst menu.

The sections below display the fields you may find creating or editing a space management job. Be aware that the sections you see, and the order in which they appear in the wizard vary depending on the selections you make and the database platform.

- New or Used Task
- Type of Space Management Task
- Database/Objects to Be Part of the Reorganization or Maintenance Task
- Custom Reorganization
- Save the OperationExecution Preferences for a Reorganization Operation
- Global Customizations
New or Used Task

Here you choose whether to create a new space management task or whether to use a previously saved task. If you want to reuse a previously created job, you can type or browse to find the previously saved task definition file (*.sptsk).

Type of Space Management Task

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create standard reorganization job</td>
<td>Select to build a reorganization job for a database or the objects you specify.</td>
</tr>
<tr>
<td>Create reorganization analyst job</td>
<td>Select to create and deploy a reorganization job that runs periodically to detect and automatically correct space inefficiencies.</td>
</tr>
<tr>
<td>Create space maintenance job</td>
<td>Select to build a space maintenance job that validates database structures and performs storage maintenance tasks.</td>
</tr>
</tbody>
</table>

Database/Objects to Be Part of the Reorganization or Maintenance Task

Choose the databases and/or objects you want to include in the job you are creating. Simply move items from the tree in the right pane to the left pane by clicking the right arrow. You can amend your selections using the left arrow. The selection is limited to entire databases for a space maintenance job.
Custom Reorganization

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform no customizations</td>
<td>When you choose this option, all default object and database attributes are used.</td>
</tr>
<tr>
<td>Perform global customizations</td>
<td>This option gives you the chance to define options that will be globally applied to all objects being reorganized.</td>
</tr>
<tr>
<td>Perform specific object customizations</td>
<td>Here you individualize options for specific objects being reorganized.</td>
</tr>
</tbody>
</table>

Save the Operation

If you want to save the operation, you can use the default name supplied or type another in the upper panel. If you don’t want to save the operation, remove the default name. Browse to the location where you want to save the file. The job as it was created appears in the read-only preview panel. To make changes, you must go back and change your selections or open the job in an ISQL window prior to execution.
Execution Preferences for a Reorganization Operation

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open the reorganization script in an ISQL editor.</td>
<td>The reorganization script will be generated and then opened in a new ISQL editing session.</td>
</tr>
<tr>
<td>Perform reorganization now</td>
<td>The reorganization is run immediately with results presented afterward in an ISQL window.</td>
</tr>
<tr>
<td>Schedule the reorganization script for later execution.</td>
<td>The reorganization script will be generated and then scheduled to run at a specified date/time.</td>
</tr>
</tbody>
</table>

Global Customizations

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relocate to file group</td>
<td>Select to perform an extended alter and move the table(s) to the requested file group using the ON keyword in the table creation DDL.</td>
</tr>
<tr>
<td>Perform sorted reorg using table's clustered index</td>
<td>Select to rebuild of any table's clustered index.</td>
</tr>
<tr>
<td>Perform online reorganization where possible</td>
<td>MICROSOFT SQL SERVER ONLY: Select to use the DBCC INDEXDEFRAG command to perform an online rebuild of every table's index(es).</td>
</tr>
<tr>
<td>View reorganization output messages</td>
<td>Select for the WITH NO_INFOMSGS clause of any DBCC command to not be used.</td>
</tr>
<tr>
<td>Defragment tables in DROP/CREATE fashion</td>
<td>Select to defragment tables in DROP/CREATE fashion.</td>
</tr>
<tr>
<td>Relocate to file group</td>
<td>Select for DROP_EXISTING clause instead of doing a drop and then create.</td>
</tr>
<tr>
<td>Fill Factor</td>
<td>Select to specify a new fill factor for the DBCC DBREINDEX command or a create/drop of an existing index.</td>
</tr>
<tr>
<td>Index Reorganization</td>
<td>Rebuild:,Drop/Create, or Reorganize</td>
</tr>
<tr>
<td>Perform online reorganization where possible</td>
<td>Select to use the DBCC INDEXDEFRAG command to perform an online rebuild of every index.</td>
</tr>
<tr>
<td>View reorganization output messages</td>
<td>Select for the WITH NO_INFOMSGS clause of any DBCC command to not be used.</td>
</tr>
</tbody>
</table>

Specific Object Customization
**Option** | **Description**
--- | ---
Select | Drop-down list lets you switch between indexes and tables and see the particular objects for each.
Relocate to file group | Select a clause instead of doing a drop and then create.
Fill Factor | For indexes, select to specify a new fill factor.
Perform sorted reorganization using table's clustered index | For tables, select to perform sorted reorganization using table's clustered index.
Index reorganization | Rebuild: This is the default. Drop/Create Reorganize
Perform online reorganization where possible | Select to perform an online rebuild of every index.
View reorganization output messages | Select for the WITH NO_INFOMSGS clause of any DBCC command to not be used.
Defragment tables in DROP/CREATE fashion | For tables, select to defragment tables in DROP/CREATE fashion.

**Threshold Criteria for Object Reorganization**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table: Average Page Density</td>
<td>Default is less than or equal to 50.</td>
</tr>
<tr>
<td>Scan Density Percent</td>
<td>Default is less than or equal to 0.</td>
</tr>
<tr>
<td>Logical Fragmentation</td>
<td>Greater than or equal to 25 is the default value.</td>
</tr>
<tr>
<td>Extent Fragmentation</td>
<td>Default is greater than or equal to 50.</td>
</tr>
<tr>
<td>Forwaded Record Percent</td>
<td>Default is greater than or equal to 50.</td>
</tr>
<tr>
<td>Index: Average Fragmentation</td>
<td>Default is greater than or equal to 25.</td>
</tr>
<tr>
<td>Scan Density Percent</td>
<td>Default is less than or equal to 0.</td>
</tr>
<tr>
<td>Logical Fragmentation</td>
<td>Greater than or equal to 25 is the default value.</td>
</tr>
<tr>
<td>Extent Fragmentation</td>
<td>Default is greater than or equal to 50.</td>
</tr>
<tr>
<td>Index Tree Depth</td>
<td>Default is greater than or equal to 3.</td>
</tr>
<tr>
<td>Average Page Density</td>
<td>Default is less than or equal to 50.</td>
</tr>
</tbody>
</table>

**Note:** All defaults are editable. Also, all current metrics for these criteria can be found on the Objects tab >Space Diagnostics view. The default thresholds are visible when you choose Threshold Options from the Space Analyst drop-down menu.
### Integrity Check Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not perform any integrity checks</td>
<td>Self-explanatory.</td>
</tr>
<tr>
<td>Check databases</td>
<td>Checks the database integrity for database(s) you identified earlier.</td>
</tr>
<tr>
<td>Check file groups</td>
<td>Self-explanatory.</td>
</tr>
<tr>
<td>Check specific database objects</td>
<td>In a later step you are able to select the particular objects.</td>
</tr>
<tr>
<td>Include index checks for all tables</td>
<td>This is the default and isn’t actually optional.</td>
</tr>
<tr>
<td>Attempt to repair minor problems</td>
<td>Enabled as a default for database or database objects integrity checks. You can unselect.</td>
</tr>
<tr>
<td>Include check for database catalogs</td>
<td>Enabled as a default for database integrity checks. You can unselect.</td>
</tr>
<tr>
<td>Correct data dictionary inaccuracies</td>
<td>Enabled as a default for database integrity checks. You can unselect.</td>
</tr>
<tr>
<td>Check data purity</td>
<td>Verifies that columns only have data in the correct ranges, and so on.</td>
</tr>
</tbody>
</table>

### Integrity Check for Specific Database Objects

Here you select objects for the database(s) you have included in this maintenance job.
Unused Space Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not eliminate unused space</td>
<td>Self-explanatory</td>
</tr>
<tr>
<td>Eliminate unused space for databases</td>
<td>Select to only truncate space for databases larger than a specific size (in MB).</td>
</tr>
<tr>
<td>Only eliminate space when database is larger than</td>
<td>Available if you selected Eliminate unused space for databases option. Lets you specify maximum database size in MB.</td>
</tr>
<tr>
<td>Amount of free space to leave for database</td>
<td>Lets you specify how much free space is to remain after a space truncation.</td>
</tr>
<tr>
<td>Eliminate unused space for specific database tables</td>
<td>Self-explanatory.</td>
</tr>
</tbody>
</table>

Problem Notification

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>No, do not notify me</td>
<td>Select to not have Space Analyst notify you of any errors.</td>
</tr>
<tr>
<td>Yes, notify me in the following ways.</td>
<td>Select to have Space Analyst notify you of any errors and then type an e-mail or net send address.</td>
</tr>
</tbody>
</table>

Space Analyst - Threshold Options

The Space Analyst Reorganization Thresholds Options dialog lets you customize the various reorganization thresholds that can be used to flag storage and data objects that need to be reorganized. The thresholds you specify will apply to the Space Analysis Reports.

Important Notes

None

The table below describes the options and functionality on the Space Analyst Thresholds Options dialog for IBM DB2 for Linux, Unix, and Windows:
space management wizard

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table Reorganization Thresholds</strong></td>
<td>The table thresholds apply to the displays used in tab 4 of the Space Analyst and the queries that are run to present the various customized displays. They are also used for the tablespace analysis report.</td>
</tr>
<tr>
<td><strong>Index Reorganization Thresholds</strong></td>
<td>The index thresholds apply to the displays used in tab 5 of the Space Analyst and the queries that are run to present the various customized displays. They are also used for the tablespace analysis report.</td>
</tr>
</tbody>

</table>

**Completing the Space Analyst Thresholds Options Dialog Box for Space Analyst**

To complete this dialog box, do the following:

1. On the Analysts Toolbar, click the Options button.

The Space Analyst opens the dialog box.

2. Review thresholds.

3. Click OK.
Space Analyst for Oracle tutorial

Embarcadero Space Analyst provides sophisticated diagnostic capabilities to troubleshoot bottlenecks and performance inefficiencies that result from poor space management. Running inside the Embarcadero DBArtisan console, Space Analyst helps you identify and correct storage problems by supplying powerful analysis facilities and corrective utilities and that will satisfy advanced experts, yet are easy enough to use for database novices.

About This Space Analyst for Oracle Tutorial

This tutorial helps you get started with Embarcadero Space Analyst.

After completion of this tutorial, you will have the foundation you need to explore the many features and benefits of Space Analyst. You will have learned how to get a summary view of storage for your database as well as how to identify potential space-related threats. Finally, you’ll use the reorganization wizard to correct any space problems that you find.

This tutorial is divided into 5 sections:

- **Session 1: Getting started With Space Analyst for Oracle**
- **Session 2: Obtaining a Global View of Storage Using Space Analyst for Oracle**
- **Session 3: Identifying Storage Structure Problems Using Space Analyst for Oracle**
- **Session 4: Pinpointing Object Performance Inefficiencies Using Space Analyst for Oracle**
- **Session 5: Correcting Space-Related Problems Using Space Analyst for Oracle**

You can use this basic tutorial as a roadmap of product highlights.

After starting this tutorial, you can select Help from the menu to find many additional resources that complement and build on many of the activities shown in this brief tutorial.
Session 1: Getting started With Space Analyst for Oracle

Download and Install

You can obtain the latest version of Space Analyst by downloading DBArtisan from the Embarcadero Web site at http://www.embarcadero.com/downloads/downloaddbartisan.asp. Space Analyst runs fully contained within DBArtisan so you will need the DBArtisan product to use Space Analyst.

Click Download, and follow the steps indicated. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for 14 days. After that time, a permanent license is needed.

Space Analyst for Oracle Overview

Once you are connected to an Oracle database, you can open Space Analyst from within DBArtisan two ways:

1. On the Analyst menu, select Space Analyst.

Note: You do not need to install anything for Space Analyst to work.

Proceed to Session 2: Obtaining a Global View of Storage Using Space Analyst for Oracle
Session 2: Obtaining a Global View of Storage Using Space Analyst for Oracle

When it opens, Space Analyst shows a complete overview of the storage situation of a particular database or database server. The first tab of Space Analyst displays all pertinent global statistics regarding storage structure usage throughout a database.

There are four distinct sections displayed on the first **Database Overview** tab of Space Analyst:

- **Database Overview**
- **Tablespace Space Overview**
- **Tablespace Fragmentation Overview**
- **Tablespace Objects Overview**

**Space Analyst for Oracle - Database Overview**

The Database Overview displays:

- The total count of all tablespaces, datafiles and temporary files.
- The percentage breakdown of the various object types in a database. Positioning the mouse pointer over the graph causes it to display the actual percentage amounts for each object type.
- The amount of space in kilobytes that each object type consumes is also shown. This section helps you get a clear picture of exactly how much space the various object types in your database are taking up.

**Tip:** If you want to see a grid-style display of the information shown in the graph, position your mouse over the graph, click the right mouse button and select the ‘toggle display’ option.

**Space Analyst for Oracle - Tablespace Space Overview**

The Tablespace Space Overview section displays summary information regarding every tablespace in the database. When invoked in graph form, this section shows how much total space is currently allocated to each tablespace. When shown in grid form, this section shows not only the total space allocated for each tablespace, but also includes the used, free, and percent free amounts, along with an indicator that shows whether any of the tablespace’s underlying data or temp files can automatically grow if necessary.
Tip: To see a grid-style display of the information shown in the graph, position your mouse over the graph, click the right mouse button and select the ‘toggle display’ option. To return to the graph, just perform the same actions over the grid.

When this section is in grid form, you can also perform a number of actions on a tablespace like open it in a DBArtisan editor, extract it’s DDL, convert it to either local or dictionary-managed, and more. For example, to open a tablespace in one of DBArtisan’s object editors, do the following:

1. In the grid, select a tablespace.
2. Right-click and select Open.

OR

3. Select a tablespace and click the Open toolbar button.

DBArtisan opens a Tablespace Editor.

Space Analyst for Oracle - Fragmentation Overview

The fragmentation overview provides a quick glance into how badly fragmented a tablespace is. Space Analyst computes a fragmentation index for every tablespace that can be used to quickly tell if fragmentation problems are plaguing a tablespace. A 100 percent reading indicates no fragmentation, while lower scores indicate the presence of fragmentation.

To see the percentage of fragmentation for each tablespace in the graph, do the following:

1. Position the pointer over each bar in the chart.

To see a grid-style display of the information shown in the graph, do the following:

1. Position the pointer over the graph.
2. Right-click and select Toggle Display.

Space Analyst for Oracle - Tablespace Objects Overview

The tablespace objects overview provides a window into the types of objects that each tablespace contains. This view is useful because it helps you quickly understand if undesired objects are present in a tablespace.

Note: There is no graphical view available for this section.

Proceed to Session 3: Identifying Storage Structure Problems Using Space Analyst for Oracle.
Session 3: Identifying Storage Structure Problems Using Space Analyst for Oracle

Space Analyst can help you quickly find storage structure problems that threaten the availability of your database.

Pinpointing ‘out of space’ Problems Using Space Analyst for Oracle

To quickly tell if any of the tablespaces in your database are about to run out of free space, do the following:

1. Select the Database Overview tab.
2. In the Tablespace Space Overview section, position the pointer over the graph.
3. Right-click and select Toggle Display.
4. Examine the Percent Free columns of each tablespace along with the Autoextend column. If a tablespace is nearing the end of free space and cannot automatically grow, take action to prevent an out-of-space error.

Locating Fragmentation Issues Using Space Analyst for Oracle

There are a number of facilities within Space Analyst that helps you understand storage structure fragmentation.

To get summary information regarding tablespace fragmentation, do the following:

1. Select the Database Overview tab.
2. In the Tablespace Fragmentation section, position the pointer over the graph.
3. Right-click and select Toggle Display.

The tablespace fragmentation grid scores each tablespace in terms of fragmentation levels and also present data regarding the number of free chunks in a tablespace along with the largest free chunk size. Tablespaces with poor fragmentation ratings are highlighted in red. Note that you can sort the grid from worst to best tablespaces by clicking on the Fragmentation Index column header in the grid.

To get the same information for datafiles, do the following:

1. Select the Data Files tab.
The datafile fragmentation grid scores each datafile in terms of fragmentation levels and also present data regarding the number of free chunks in the datafile along with the largest free chunk size. Note that temp files are not shown in this display. Datafiles with poor fragmentation ratings are highlighted in red.

To determine the type of fragmentation for a tablespace (bubble or honeycomb), do the following:

1. Select a tablespace or datafile that appears to have fragmentation issues.
2. Right-click and select Map.

Space Analyst displays a graphical rendering of the tablespace on the **Tablespace Map** tab.

Bubble fragmentation can be confirmed by the presence of many free space fragments being found throughout the tablespace. Honeycomb fragmentation can be identified by seeing free space fragments adjacent to one another in the map.

**Note:** Large tablespace maps can be read easier if the “Full Screen” option is chosen. The standard view may be returned from full screen by clicking on the small full screen dialog box that appears at the upper left side of the display.

Note that object extent fragmentation problems can also be identified in Space Analyst’s tablespace map. To see if any table or index in a designated tablespace suffers from extent fragmentation, do the following:

1. Select the **Tablespace Map** tab.
2. Select a tablespace.
3. In the View By section, select the Extent Problems option.

Space Analyst reconstructs the tablespace map and accompanying left-hand object grid to reveal any objects that have extent problems. All objects with extent problems are color-coded in red for easy identification. Objects colored in green indicate that they do not suffer from any extent problems.

**Using Analysis Reports in Space Analyst for Oracle**

You can run HTML-formatted reports that pinpoint all major storage-related problems for a particular tablespace and the objects that are contained within it. To produce an Analysis Report, do the following:

Space Analyst opens the **Analysis Report** dialog.

2. In Report File Name and Report Title you can change the location and report title of the report.

3. In Category, select the types of space problems you would like to investigate. The default option is All.
4. In Tablespace, select the tablespace you would like to analyze.

5. Click Execute.

Space Analyst creates a frame-based Analysis report for the tablespace.

Proceed to Session 4: Pinpointing Object Performance Inefficiencies Using Space Analyst for Oracle
Session 4: Pinpointing Object Performance Inefficiencies Using Space Analyst for Oracle

Space Analyst can greatly accelerate the process of locating objects in your database that are degrading overall response times because of their current storage/space situation.

Finding Space-related Table Problems With Space Analyst for Oracle

To quickly determine if any tables in your database may be contributing to performance slowdowns, do the following:

1. In DBArtisan connect to the database you would like to check.
2. Open Space Analyst.
3. Select the Tables tab.

Space Analyst runs diagnostics against your database and graphically display counts of tables that are found to contain various types of space problems.

The graph at the top of the Tables tab shows the overall count of problem tables, but you can also view the details for each type of problem by using the Details grid at the bottom of the tab. For example, if Space Analyst identifies tables that have block inefficiencies, to find the actual tables and view details regarding the identified space problem, do the following in the Details grid:

1. In the Tablespace list, select All.
2. In the Table Owner list, select All.
3. In the Display list, select Tables with inefficient block usage.
4. Click Execute.

Space Analyst displays the actual tables that suffer from block inefficiencies along with their demographic details. To take corrective action on any object, select one or more tables and click the right mouse button to bring up a menu of possible actions.

Finding Space-related Index Problems with Space Analyst for Oracle

To quickly determine if any indexes in your database may be contributing to performance slowdowns by following these steps:
1. In DBArtisan connect to the database you would like to check.

2. Open Space Analyst.

3. Select the **Indexes** tab.

The graph at the top of the **Indexes** tab shows the overall counts of problem indexes, but you can also view the details for each type of problem by using the Details grid at the bottom of the tab. For example, if Space Analyst identifies indexes that have next extent problems, then to find the actual indexes and view details regarding the space problem, do the following in the Details grid:

1. In the Tablespace list, select All.
2. In the Index Owner list, select All.
3. In the Display list, select Indexes with NEXT_EXTENT space deficits.
4. Click Execute.

Space Analyst displays the actual indexes that suffer from next extent space problems along with their demographic details. If you wanted to take corrective action on any object, select one or more indexes and click the right mouse button to bring up a menu of possible actions.

**Note:** Another critical statistic in determining index problems is deleted leaf rows. To display deleted leaf row statistics in the Details grid, do the following:

- On the Command toolbar, select Get Deleted Leaf Row Statistics.

Proceed to **Session 5: Correcting Space-Related Problems Using Space Analyst for Oracle**
Session 5: Correcting Space-Related Problems Using Space Analyst for Oracle

After you have identified space-related bottlenecks in your database with Space Analyst, you can use a number of different tools and facilities within the product to eliminate each storage problems.

Correcting Storage Structure ‘out of space’ Problems for Space Analyst for Oracle

Space Analyst can help you quickly remedy tablespaces that are running out of room by:

- Resizing an existing tablespace to have more room.
- Adding a new datafile to an existing tablespace.
- Setting the Autoextend attribute for one or more of a tablespace’s datafiles to allow for automatic growth.

To manage these functions, do the following:

1. Select the **Database Overview** tab.
2. In the Tablespace Space Overview section, right-click the graph, and then select **Toggle Display**.
3. Select the tablespace that is running low on free space.
4. Select the Open toolbar button or the Open shortcut menu option.

DBArtisan opens a Tablespace Editor.

In the Tablespace Editor, you can remedy the tablespace problem three ways:

- To resize an existing tablespace, open the tablespace’s datafile in the editor (using the Edit button) and change the datafile’s size to a new, larger size. Then close the editor and select the Alter toolbar button to make the change permanent to the database.

- To add a new datafile to the tablespace, select the Add button in the **Datafile** tab of the tablespace editor, and specify the new datafile’s attributes. Once complete, close the Add Datafile dialog and select the Alter toolbar button to make the change permanent to the database.

- To set Autoextend for one or more of a tablespace’s datafiles, open each datafile in the datafile editor by selecting the Edit button. Once in the Modify Datafile dialog, select the option for Auto Extend and specify other attributes as
needed. When complete, close the dialog and select the Alter toolbar button to make the change permanent to the database.

Correcting Storage Structure Fragmentation Issues Using Space Analyst for Oracle

Space Analyst can help you quickly fix tablespaces that are suffering from fragmentation by:

- Coalescing adjacent free space fragments (honeycombs) in a tablespace
- Reorganizing a tablespace to eliminate free space bubbles
- Converting a dictionary-managed tablespace to locally-managed

To coalesce free space fragments in a tablespace, follow these steps:

1. On the **Database Overview** tab, select any tablespace that appears to be suffering from fragmentation problems.
2. Select the Open toolbar button or the Open shortcut menu option. DBArtisan opens a Tablespaces Editor.
3. To view fragmentation details for the tablespace, click the **Space** tab of the Tablespaces Editor.
4. To combine adjacent free space pockets into singular free space chunks, click the Coalesce button.

**Note:** The fragmentation score of the tablespace does not change after a coalesce operation, then the tablespace likely suffers from bubble fragmentation. This can be verified by viewing the tablespace map for the tablespace.

To reorganize any tablespace suffering from bubble fragmentation, do the following:

1. On the toolbar, click the Open Wizard button. Space Analyst opens the Reorganization Wizard.
2. Select the New Reorganization option, and then click Next to continue.
3. Select Reorganize a Tablespace, and then click Next to continue.
4. Select one or more tablespaces you would like to reorganize, and then click Next to continue.
5. Select a scratch tablespace that temporarily holds the reorganized tablespace’s objects.
6. Select the option to perform a space analysis so you can be assured that the scratch tablespace has enough room to temporarily hold all of the reorganized tablescape’s objects.

7. If the selected scratch tablespace does not contain enough free space, select another tablespace to serve as the scratch tablespace.

8. Click Next to continue.

Space Analyst opens the next panel of the Reorganization Wizard.

9. You can choose to perform no customizations for the reorganization, or you can select various global or object-level options to customize your reorganization.

10. Click Finish.

Space Analyst builds a reorganization script to reorganize your selected tablespace. Note that while the script is being constructed, you can still perform other work in Space Analyst or DBArtisan. Just minimize the script build window and continue to do other work in DBArtisan. You can check back whenever you’d like to see if the script is ready.

After the reorganization script is complete, you can choose to view/run the script in a DBArtisan ISQL window, schedule the script for later execution, or immediately execute the reorganization.

If you would like to convert a dictionary-managed tablespace to locally-managed, you can do one of the following:

- Create a new locally-managed tablespace in DBArtisan and then use the Reorganization Wizard to permanently relocate all objects from the dictionary-managed tablespace to the new locally-managed tablespace. This is the cleanest method for converting a dictionary-managed tablespace to locally-managed.

- Choose the option in Space Analyst that allows a quick conversion of an existing dictionary-managed tablespace to a locally-managed tablespace. This option is only available for Oracle versions 8.1.6 or later. This option does not defragment an existing dictionary-managed tablespace, but converts it so that all space management is conducted through the tablespace’s datafiles instead of the data dictionary and ensure that any new objects added to the tablespace conform to the tablespace’s storage attributes.

**Correcting Space-Related Object Problems for Space Analyst for Oracle**

Space Analyst can help you quickly fix objects that are experiencing space problems by:

- Modifying various storage-related properties for an object.
- Reorganizing the object to eliminate space inefficiencies.

Storage properties that are affecting the availability of an object (for example, the next extent or maximum extent values for a table or index) can easily be altered by using the
integration that exists between Space Analyst and DBArtisan. For example, to modify a table’s next extent value, do the following:

1. On the **Tablespace Map** tab or the Table Details grid on the **Tables** tab, select a table you would like to alter.

2. Select the Open toolbar button or the Open shortcut menu option. DBArtisan opens a Tables Editor.

3. Select the **Storage** tab.

4. Change the numeric value for the table’s next extent.

**Note:** You cannot change next extent values for tables that exist in locally-managed tablespaces.

5. On the toolbar, click the Alter button. DBArtisan displays the DDL that change the table’s next extent value.

You can easily reorganize one or more objects with the Reorganization Wizard. To reorganize any table or index that in any grid, do the following:

1. Select the object(s).

2. On the toolbar, click the Reorganization Wizard button, or right-click and select Reorganize. Space Analyst opens the Reorganization Wizard.

You can customize object reorganizations by using either the global or specific object customization options in the Reorganization Wizard. For example, you can perform online reorganizations of indexes or index-organized tables.

Space Analyst’s Reorganization Wizard can also intelligently identify objects that need to be reorganized. For example, to reorganize tables in your database that have chained/migrated rows, do the following:

1. On the toolbar, click the Reorg Wizard button. Space Analyst opens the Reorganization Wizard.

2. Select the New Reorganization option, and then click Next to continue. Space Analyst opens the next panel of the Reorganization Wizard.

3. Select Repair tables with chained/migrate rows, and then click Next to continue. Space Analyst runs diagnostics against your database to find any table or table partition that suffers from chained rows. Space Analyst displays the objects under either the Tables or Table Partition(s) node in the Reorg Wizard explorer tree. You can then select one or all table objects and continue with the reorganization process.
Space Analyst for Microsoft SQL Server Tutorial

Embarcadero Space Analyst provides sophisticated diagnostic capabilities to troubleshoot bottlenecks and performance inefficiencies that result from poor space management. Running inside the Embarcadero DBArtisan console, Space Analyst helps you identify and correct storage problems by supplying powerful analysis facilities and corrective utilities and that will satisfy advanced experts, yet are easy enough to use for database novices.

Space Analyst for Microsoft Product Benefits

Embarcadero Space Analyst allows the database administrator to quickly ascertain if space problems are threatening the availability or performance of their key databases. If storage problems are found, Space Analyst provides powerful but easy to use space management wizards and utilities that can accomplish simple or complex reorganizations of all or parts of a database.

About this Space Analyst for Microsoft Tutorial

This tutorial helps you get started with Embarcadero Space Analyst.

After completion of this tutorial, you will have the foundation you need to explore the many features and benefits of Space Analyst. You will have learned how to get a summary view of storage for your database as well as how to identify potential space-related threats. Finally, you’ll use the reorganization wizard to correct any space problems that you find.

This tutorial is divided into 5 sections:

- Session 1: Getting Started with Space Analyst
- Session 2: Obtaining a Global View of Storage
- Session 3: Identifying Storage Structure Problems
- Session 4: Pinpointing Object Performance Inefficiencies
- Session 5: Correcting Space-Related Problems

You can use this basic tutorial as a roadmap of product highlights.

After starting this tutorial, you can select Help from the menu to find many additional resources that complement and build on many of the activities shown in this brief tutorial.
Session 1: Getting started with Space Analyst for Microsoft

Download and Install

You can obtain the latest version of Space Analyst by downloading DBArtisan from the Embarcadero Web site at http://www.embarcadero.com/downloads/downloaddbartisan.asp. Space Analyst runs fully contained within DBArtisan so you will need the DBArtisan product to use Space Analyst.

Click Download, and follow the steps indicated. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for 14 days. After that time, a permanent license is needed.

Space Analyst for Microsoft Overview

Once you are connected to an Microsoft SQL Server database, you can open Space Analyst from within DBArtisan two ways:

1. On the Analyst menu, select Space Analyst.

Note: You do not need to install anything for Space Analyst to work.

Proceed to Session 2: Obtaining a Global View of Storage Using Space Analyst for Microsoft
Session 2: Obtaining a Global View of Storage Using Space Analyst for Microsoft

When first invoked, Space Analyst displays a complete overview of the storage situation of a particular SQL Server. The first tab of Space Analyst can be used to see all pertinent global statistics regarding storage structure usage throughout a server.

There are four distinct sections displayed on the first tab (labeled Storage Overview) of Space Analyst:

- **Server Overview**
- **Database Overview**
- **Log Overview**
- **Server Disk Overview**

**Space Analyst for Microsoft - Server Overview**

The total count of all databases, file groups, and files are shown in this section. You can also see the percentage breakdown of the database vs. log space on the server. Positioning the mouse pointer over the graph causes it to display the actual percentage amounts for storage type.

**Tip:** If you want to see a grid-style display of the information shown in most graphs, position your mouse over the graph, click the right mouse button and select the 'toggle display' option.

**Space Analyst for Microsoft - Database Overview**

Summary information regarding every database on the server is present in the database overview section. When invoked in graph form, this section shows how much total space is used by each database. When shown in grid form, this section shows not only the total space used for each database, but also includes the total allocated, free, and percent free amounts, along with an indicator that shows whether any of the database’s underlying datafiles can automatically grow if necessary.

**Tip:** To see a grid-style display of the information shown in the graph, position your mouse over the graph, click the right mouse button and select the ‘toggle display’ option. To return to the graph, just perform the same actions over the grid.

When this section is in grid form, you can also perform a number of actions on a database like open it in a DBArtisan editor, extract its DDL, shrink it, and more. For example, if you want to open a database in DBArtisan’s database manager, do the following:
1. In the grid, select a database.
2. Right-click and select Open.

OR

3. Select a database and click the Open toolbar button.

DBArtisan opens the Database Manager.

**Space Analyst for Microsoft - Log Overview**

The log overview provides a quick glance into database transaction log usage. When invoked in graph form, this section shows the percentage of used log space per database. When shown in grid form, this section shows not only the total percentage of transaction log space used for each database, but also includes the total allocated and free amounts (in MB), along with an indicator that shows whether any of the database’s transaction logs underlying log files can automatically grow if necessary.

**Space Analyst for Microsoft - Server Disk Overview**

The server disk overview provides a window into how much free space exists on the actual server machine. In graph form, this section shows the amount of free space (in MB) across each of the server’s drives. When in grid form, it shows free space per drive, but also includes the amount of allocated SQL Server data and log space per drive.

Proceed to [Session 3: Identifying Storage Structure Problems in Space Analyst for Microsoft](#)
Session 3: Identifying Storage Structure Problems in Space Analyst for Microsoft

Space Analyst can help you quickly find storage structure problems that threaten the availability of your database.

Pinpointing ‘out of space’ Problems Using Space Analyst for Microsoft

To quickly tell if any of the tablespaces in your database are about to run out of free space, do the following:

1. Select the **Storage Overview** tab.
2. In the Database Overview and Log Overview sections, position the pointer over the graph.
3. Right-click and select Toggle Display.

Examine the Percent DB Used columns of each database and transaction log along with the DB Can Grow column. If a database or transaction log is nearing the end of free space and cannot automatically grow, then action should be taken to prevent an out-of-space error.

You can also obtain graphical views of databases and pertinent storage property information by viewing the **Databases** tab of Space Analyst. You can visually get a handle on the amounts of table, index, and free space of your databases and quickly view critical storage property facts such as the number of databases that cannot automatically grow in size if needed.

All the graphs can be toggled to grids by using the right mouse menu option of Toggle Display. When in grid mode, very detailed information is available concerning database and transaction log space. Note that the graph is scrollable so you may have to scroll to see all your databases.

You can perform a number of actions on a database, such as shrinking it or invoking database-related DBCC operations by using either the right mouse menu or the Command toolbar button (the yellow arrow).

Viewing Filegroup and File Details Using Space Analyst for Microsoft

You can also view space usage at the filegroup and file levels. To get summary and detailed information for filegroups and files, follow these steps:

1. Invoke Space Analyst and view the **File Groups/Files** tab.
The default presentation is a graphical overview of filegroups. Note that the graph is scrollable so you may have to scroll to see all your filegroups.

2. To view detailed information for filegroups, right-click and select Toggle Display to view the grid.

3. To view file information instead of filegroup metrics, select Files.

When viewing filegroup and file information, you can perform a number of actions on selected filegroups and files such as extracting their DDL or shrinking the parent database or selected file. All options are available by using either the shortcut menu or Command menu.

**Using Analysis Reports in Space Analyst for Microsoft**

You can run HTML-formatted reports that pinpoint all major storage-related problems for a particular tablespace and the objects that are contained within it. To produce an Analysis Report, do the following:

Space Analyst opens the **Analysis Report** dialog.

2. In Report File Name and Report Title you can change the location and report title of the report.

3. In Category, select the types of space problems you would like to investigate. The default option is All.

4. In Database, select the database you would like to analyze.

5. In File Group, select the filegroup level.

6. Click Execute.

Space Analyst creates a frame-based Analysis report for the database.

Proceed to **Session 4: Pinpointing Object Performance Inefficiencies Using Space Analyst for Microsoft**
Session 4: Pinpointing Object Performance Inefficiencies Using Space Analyst for Microsoft

Space Analyst can greatly accelerate the process of locating objects in your databases that are degrading overall response times because of their current inefficient storage usage.

Finding Space-related Table Problems with Space Analyst for Microsoft

To quickly determine if any tables in your database may be contributing to performance slowdowns, do the following:

1. Open Space Analyst.
2. Select the Objects tab.
3. In Object Details, select the target object.

By default, the General Space button is selected. This view will show you a graphical layout of table used and free space for the database. Note that the graph is scrollable so you can scroll to see all the tables for your database.

The Object details grid in the lower area of the tab can be used to view detailed storage information for every table in the selected database.

To troubleshoot table storage issues in your database, select the Space Diagnostics radio button. This option will interrogate your database and will provide you with a graphical count of the number of tables that are experiencing specific types of storage inefficiencies. Space Analyst uses predefined thresholds (which you can customize by selecting the Threshold Options toolbar button) to determine how many and what objects are suffering from storage inefficiencies.

The table below describes the types of table-related space problems shown in the bar graph found on the Objects Tab:
<table>
<thead>
<tr>
<th>Problem</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan Density</td>
<td>This is computed by dividing the optimum number of extent switches by the actual number of extent switches. This percentage can be misleading, however, if the object spans more than one database file and should not be considered in such an event. Values close to 100% are best.</td>
</tr>
<tr>
<td>Logical Fragmentation</td>
<td>This metric represents the percentage of pages that are out of physical order. High values (greater than 25%) for this metric may mean that index scan performance is not what it could be. Note that this statistic is meaningless for tables without clustered indexes (heap tables).</td>
</tr>
<tr>
<td>Extent Fragmentation</td>
<td>This highlights any gaps (lack of contiguous order) in extents and indicates the presence of external fragmentation. Percentages of 25-50% or more are not a favorable reading.</td>
</tr>
<tr>
<td>Average Page Density</td>
<td>This metric represents the fullness of the data or index pages, and is an indicator of internal fragmentation. Remember that the more full a data or index page is, the less I/O needed by SQL Server when performing scans of tables or indexes. High values are good here, with anything below 50% being suspect. Low values for this metric often indicate the presence of page splitting. Keep in mind, however, that internal fragmentation isn't necessarily bad in OLTP environments where large FILLFACTORs are often specified. Also understand that small objects (those will little or no data) will likely show low readings because they simply don't consume enough space in a database page. You can ignore these objects.</td>
</tr>
<tr>
<td>Forwarded Records</td>
<td>SQL Server will move rows in a table under certain conditions. One situation might arise when you update a row in a table that has a variable-length column to a larger size that will no longer fit on its original page. Another situation would be if SQL Server moves a row when the clustered index column changes. Forwarded records can reduce performance at times because additional I/O is involved to first obtain the record pointer to the relocated row, and then the row itself. But when does row forwarding become a problem? For example, just because a table has one hundred forwarded rows, does that mean a performance problem exists? The answer is: it depends. If the table has one hundred rows in it, then yes, a problem exists - 100% of the table suffers from forwarded rows. If the table has three million rows, then the forwarded row situation is likely not causing much fuss in the database.</td>
</tr>
</tbody>
</table>

The graph at the top of the **Objects** tab shows the overall count of problem tables, but you can also view the details for each type of problem by using the Details grid at the bottom of the tab. For example, if Space Analyst identifies tables that have forwarded records, then to find the actual tables and view details regarding the identified space problem, do the following:

1. In the File Group list, select All.
2. In the Owner list, select All.
3. In the Display list, select Tables with forwarded records problems.
4. Click Refresh.
You would then see the actual tables that suffer from forwarded records along with their demographic details. If you wanted to take corrective action on any object, you could highlight one or more tables and click the right mouse button to bring up a menu of possible actions.

Proceed to Session 5: Correcting Space-related Problems Using Space Analyst for Microsoft
Session 5: Correcting Space-related Problems Using Space Analyst for Microsoft

After you have identified space-related bottlenecks in your database with Space Analyst, you can use a number of different tools and facilities within the product to eliminate each storage problems.

Correcting Storage Structure ‘out of space’ Problems Using Space Analyst for Microsoft

Space Analyst can help you quickly remedy databases and transaction logs that are running out of room by:

- Resizing an existing database or transaction log to have more room.
- Adding a new filegroup or file to an existing database or transaction log.
- Setting the Autogrowth attribute for one or more of a database’s or transaction log’s files to allow for automatic growth.

To manage these functions, do the following:

1. Select the Databases tab.
2. In the Database Summary section, right-click the graph, and then select Toggle Display.
3. Select the database that is running low on free space.
4. Select the Open toolbar button or the Open shortcut menu option.

DBArtisan opens the Database Manager.

In the Database Manager, you can remedy the database problem in one of three ways:

- To resize an existing database or transaction log, open one of the database’s or log’s files in the editor (using the Edit button) and change the file’s size to a new, larger size. Then close the editor and select the Alter toolbar button to make the change permanent to the database.
- To add a new file or file group to the database or transaction log (note: you can’t add new filegroups to a transaction log, only files), select the Add button in the editor, and specify the new filegroup or file’s attributes. Once complete, close the Add Datafile dialog and select the Alter toolbar button to make the change permanent to the database.
- To set Autogrowth for one or more of a database’s or transaction log’s files, open each file in the file editor by selecting the file and then pressing the Edit...
button. Once in the Modify File dialog, select the option for Allow Growth and specify other attributes as needed. When complete, close the dialog and select the Alter toolbar button to make the change permanent to the database.

Removing Wasted Space in Databases or Files Using Space Analyst for Microsoft

Space Analyst can help you quickly eliminate unused space in a database or database file. The unused space can be released back to the operating system for other use. To remove unused space from a database, do the following:

1. To shrink an entire database, right-click a database in any of Space Analyst’s grids, and then select Shrink Database.

DBArtisan opens the Shrink File dialog.

2. To shrink a specific file in a database, select the Filegroups/Files tab and then view files by selecting the Files radio button.

3. Right-click a file and select Shrink File.

DBArtisan opens the Shrink File dialog.

4. Select desired options.

5. Click Execute to make the change permanent.

Correcting Space-related Object Problems for Space Analyst for Microsoft

Once you identify specific objects that need storage corrections, you can use Space Analyst to help you quickly resolve your found issues. The Space Management wizard inside of Space Analyst can be used to build reorganization and space maintenance jobs that run right the first time. All jobs can either be immediately run or scheduled for later execution.

To create a standard database or object reorganization job, do the following:

1. Click the Open Wizard button.

2. Select New Space Management Task.

3. Click Next.

4. Select Create standard reorganization job.

5. Click Next.

6. Select the databases and objects you would like to reorganize from the Explorer tree on the left hand side of the wizard. You can reorganize full databases, selected schema accounts, or selected objects.
7. Click Next.

8. The next panel allows you to customize the reorganization. You can either set options at the global level (affects all objects) or specific object level. Using the options, you can relocate objects to different filegroups, perform online index rebuilds, and specify other customizations.

9. Click Next.

10. The next panel builds your reorganization script and allows you to preview the operation. Click Next when ready.

11. Click Next.

The final panel allows you to open the reorganization script in a SQL editor, immediately run it, or schedule it for later execution.

Proactive Space Management Using Space Analyst for Microsoft

If you have many databases to take care of, then you might want to relieve the burden of performing detailed storage analysis on every database, each of which may or may not require attention. Fortunately, Space Analyst makes it easy to create smart space management jobs that can automate this task for you.

You can create two specialized space management jobs that allow you to proactively eliminate space threats before they affect your database:

You can create a "reorganization analyst job" that allows you to specifically select various databases and/or objects and then set reorganization thresholds that determine when a reorganization will occur. Once constructed, you can schedule these jobs to run as often as you’d like. During execution, these jobs will interrogate your chosen database/objects and determine if a reorganization needs to occur by applying your customized reorganization thresholds. If any objects are found to need reorganization, they are dynamically reorganized using any customized options you specify.

You can build space maintenance jobs that will perform functions such as check the validity of your databases and filegroups, repair any found minor corruption, and eliminate unused space in your databases. You can also set the job up to notify you if any problems are found during job execution.

These "smart" space maintenance jobs allow you to truly "set and forget" the task of monitoring and reorganizing the space of your critical databases.
Space Analyst for Sybase ASE Tutorial

Embarcadero Space Analyst provides sophisticated diagnostic capabilities to troubleshoot bottlenecks and performance inefficiencies that result from poor space management. Running inside the Embarcadero DBArtisan console, Space Analyst helps you identify and correct storage problems by supplying powerful analysis facilities and corrective utilities and that will satisfy advanced experts, yet are easy enough to use for database novices.

Space Analyst for Sybase ASE Product Benefits

Embarcadero Space Analyst allows the database administrator to quickly ascertain if space problems are threatening the availability or performance of their key databases. If storage problems are found, Space Analyst provides powerful but easy to use space management wizards and utilities that can accomplish simple or complex reorganizations of all or parts of a database.

About this Space Analyst for Sybase ASE Tutorial

This tutorial helps you get started with Embarcadero Space Analyst.

After completion of this tutorial, you will have the foundation you need to explore the many features and benefits of Space Analyst. You will have learned how to get a summary view of storage for your database as well as how to identify potential space-related threats. Finally, you’ll use the reorganization wizard to correct any space problems that you find.

This tutorial is divided into 4 sections.

- **Session 1: Getting Started With Space Analyst for Sybase ASE**
- **Session 2: Obtaining a Global View of Storage Using Space Analyst for Sybase ASE**
- **Session 3: Identifying Storage Structure Problems in Space Analyst for Sybase ASE**
- **Session 4: Correcting Space-related Problems Using Space Analyst for Sybase ASE**

You can use this basic tutorial as a roadmap of product highlights.

After starting this tutorial, you can select Help from the menu to find many additional resources that complement and build on many of the activities shown in this brief tutorial.
Session 1: Getting Started With Space Analyst for Sybase ASE

Download and Install

You can obtain the latest version of Space Analyst by downloading DBArtisan from the Embarcadero Web site at http://www.embarcadero.com/downloads/downloaddbartisan.asp. Space Analyst runs fully contained within DBArtisan so you will need the DBArtisan product to use Space Analyst.

Click Download, and follow the steps indicated. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for 14 days. After that time, a permanent license is needed.

Space Analyst for Sybase ASE Overview

The graphic below illustrates all the main elements of the DBArtisan User Interface.

Once you are connected to an Sybase ASE database, you can open Space Analyst from within DBArtisan two ways:

1. On the Analyst menu, select Space Analyst.

Note: You do not need to install anything for Space Analyst to work.

Proceed to Session 2: Obtaining a Global View of Storage Using Space Analyst for Sybase ASE
Session 2: Obtaining a Global View of Storage Using Space Analyst for Sybase ASE

When first invoked, Space Analyst displays a complete overview of the storage situation of a particular server. The first tab of Space Analyst can be used to see all pertinent global statistics regarding storage structure usage throughout a server.

There are four distinct sections displayed on the Storage Overview tab of Space Analyst:

- **Server Overview**
- **Log Overview**
- **Database Overview**
- **Device Overview**

Space Analyst for Sybase ASE - Server Overview

The total count of all databases, file groups, and files are shown in this section. You can also see the percentage breakdown of the database vs. log space on the server. Positioning the mouse pointer over the graph causes it to display the actual percentage amounts for storage type.

**Tip:** If you want to see a grid-style display of the information shown in most graphs, position your mouse over the graph, click the right mouse button and select the 'toggle display' option.

Proceed to **Space Analyst for Sybase ASE - Log Overview**

Space Analyst for Sybase ASE - Log Overview

The log overview provides a quick glance into database transaction log usage. When invoked in graph form, this section shows the percentage of used log space per database. When shown in grid form, this section shows not only the total percentage of transaction log space used for each database, but also includes the total allocated and free amounts (in MB), along with an indicator that shows whether any of the database’s transaction logs underlying log files can automatically grow if necessary.

Space Analyst for Sybase ASE - Database Overview

Summary information regarding every database on the server is present in the database overview section. When invoked in graph form, this section shows how much total space is used by each database. When shown in grid form, this section shows not only the total space used for each database, but also includes the total allocated, free, and percent
free amounts, along with an indicator that shows whether any of the database’s underlying datafiles can automatically grow if necessary.

**Tip:** To see a grid-style display of the information shown in the graph, position your mouse over the graph, click the right mouse button and select the ‘toggle display’ option. To return to the graph, just perform the same actions over the grid.

When this section is in grid form, you can also perform a number of actions on a database like open it in a DBArtisan editor, extract its DDL, shrink it, and more. For example, if you want to open a database in DBArtisan’s database manager, do the following:

1. Select a database, right-click, and select Open.

OR

2. Select a database and click the Open toolbar button.

DBArtisan opens the Database Manager.

**Space Analyst for Sybase ASE - Device Overview**

The device overview section contains a graphical and grid control that works in the following way:

- When the graph is displayed, a bar chart is shown that lists the total space used (in MB) of all devices defined to the server.

- When the grid is displayed, detailed storage information for each database device is presented:
  - Device name
  - Physical name
  - Total space
  - Used space
  - Free space
  - Percent free
  - Percent used

Proceed to [Session 3: Identifying Storage Structure Problems in Space Analyst for Sybase ASE](#)
Session 3: Identifying Storage Structure Problems in Space Analyst for Sybase ASE

Space Analyst can help you quickly find storage structure problems that threaten the availability of your database.

Pinpointing ‘out of space’ Problems Using Space Analyst for Sybase ASE

To quickly tell if any of the tablespaces in your database are about to run out of free space, do the following:

1. Select the Storage Overview tab.
2. In the Database Overview and Log Overview sections, position the pointer over the graph.
3. Right-click and select Toggle Display.

Examine the Database Percent Free columns of each database and Log Percent Free for each transaction log. If a database or transaction log is nearing the end of free space and cannot automatically grow, then action should be taken to prevent an out-of-space error.

You can also obtain graphical views of databases and pertinent storage property information by viewing the Databases tab of Space Analyst. You can visually get a handle on the amounts of table, index, and free space of your databases and quickly view critical storage property facts such as the number of databases that cannot automatically grow in size if needed.

All the graphs can be toggled to grids by using the right mouse menu option of ‘Toggle Display’. When in grid mode, very detailed information is available concerning database and transaction log space. Note that the graph is scrollable so you may have to scroll to see all your databases.

Using Analysis Reports in Space Analyst for Sybase ASE

You can run HTML-formatted reports that pinpoint all major storage-related problems for a particular tablespace and the objects that are contained within it. To produce an Analysis Report, do the following:

Space Analyst opens the Analysis Report dialog.
2. In Report File Name and Report Title you can change the location and report title of the report.

3. In Category, select the types of space problems you would like to investigate. The default option is All.

4. In Database, select the database you would like to analyze.

5. In File Group, select the filegroup level.

6. Click Execute.

Space Analyst creates a frame-based Analysis report for the database.

Proceed to Session 4: Correcting Space-related Problems Using Space Analyst for Sybase ASE.
Session 4: Correcting Space-related Problems Using Space Analyst for Sybase ASE

After you have identified space-related bottlenecks in your database with Space Analyst, you can use a number of different tools and facilities within the product to eliminate each storage problems.

Correcting Storage Structure ‘out of space’ Problems Using Space Analyst for Sybase ASE

Space Analyst can help you quickly remedy databases and transaction logs that are running out of room by:

- Resizing an existing database or transaction log to have more room.
- Adding a new filegroup or file to an existing database or transaction log.
- Setting the Autogrowth attribute for one or more of a database’s or transaction log’s files to allow for automatic growth.

To manage these functions, do the following:

1. Select the Storage Overview tab.
2. In the Database Overview or Log Overview section, right-click the graph, and then select Toggle Display.
3. Select the database that is running low on free space.
4. Select the Open toolbar button or the Open shortcut menu option.

DBArtisan opens the Database Manager.

In the Database Manager, you can remedy the database problem in one of three ways:

- To resize an existing database or transaction log, open one of the database’s or log’s files in the editor (using the Edit button) and change the file’s size to a new, larger size. Then close the editor and select the Alter toolbar button to make the change permanent to the database.

- To add a new file or file group to the database or transaction log (note: you can’t add new filegroups to a transaction log, only files), select the Add button in the editor, and specify the new filegroup or file’s attributes. Once complete, close the Add Datafile dialog and select the Alter toolbar button to make the change permanent to the database.

- To set Autogrowth for one or more of a database’s or transaction log’s files, open each file in the file editor by selecting the file and then pressing the Edit
button. Once in the Modify File dialog, select the option for Allow Growth and specify other attributes as needed. When complete, close the dialog and select the Alter toolbar button to make the change permanent to the database.

Correcting Space-related Object Problems for Space Analyst for Sybase ASE

Once you identify specific objects that need storage corrections, you can use Space Analyst to help you quickly resolve your found issues. The Space Management wizard inside of Space Analyst can be used to build reorganization and space maintenance jobs that run right the first time. All jobs can either be immediately run or scheduled for later execution.

To create a standard database or object reorganization job, do the following:

1. Click the Open Wizard button.
2. Select New Space Management Task.
3. Click Next.
4. Select Create standard reorganization job.
5. Click Next.
6. Select the databases and objects you would like to reorganize from the Explorer tree on the left hand side of the wizard. You can reorganize full databases, selected schema accounts, or selected objects.
7. Click Next.
8. The next panel allows you to customize the reorganization. You can either set options at the global level (affects all objects) or specific object level.
9. Click Next.
10. The next panel builds your reorganization script and allows you to preview the operation. Click Next when ready.
11. Click Next.

The final panel allows you to open the reorganization script in a SQL editor, immediately run it, or schedule it for later execution.

Proactive Space Management Using Space Analyst for Sybase ASE

If you have many databases to take care of, then you might want to relieve the burden of performing detailed storage analysis on every database, each of which may or may not require attention. Fortunately, Space Analyst makes it easy to create smart space management jobs that can automate this task for you.
You can create two specialized space management jobs that allow you to proactively eliminate space threats before they affect your database:

You can create a "reorganization analyst job" that allows you to specifically select various databases and/or objects and then set reorganization thresholds that determine when a reorganization will occur. After completion of this tutorial, you will have the foundation you need to explore the many features and benefits of Space Analyst. You will have learned how to get a summary view of storage for your database as well as how to identify potential space-related threats. Finally, you’ll use the reorganization wizard to correct any space problems that you find.

This tutorial is divided into 5 sections.

- **Session 1: Getting Started with Space Analyst**
- **Session 2: Obtaining a Global View of Storage**
- **Session 3: Identifying Storage Structure Problems**
- **Session 4: Pinpointing SQL server Performance Inefficiencies**
- **Session 5: Correcting Space-related Problems**

You can use this basic tutorial as a roadmap of product highlights.

After starting this tutorial, you can select Help from the menu to find many additional resources that complement and build on many of the activities shown in this brief tutorial.
Session 1: Getting Started with Space Analyst for IBM DB2 for Linux, Unix, and Windows

Download and Install

You can obtain the latest version of Space Analyst by downloading DBArtisan from the Embarcadero Web site at http://www.embarcadero.com/downloads/downloaddbartisan.asp. Space Analyst runs fully contained within DBArtisan so you will need the DBArtisan product to use Space Analyst.

Click Download, and follow the steps indicated. Save the file on your computer and then double-click to launch the self-extracting file that will guide you through the installation process.

When you first install an evaluation copy of DBArtisan, you can use the tool for 14 days. After that time, a permanent license is needed.

Space Analyst for IBM DB2 for Linux, Unix, and Windows Overview

Once you are connected to an IBM DB2 for Linux, Unix, and Windows database, you can open Space Analyst from within DBArtisan two ways:

1. On the Analyst menu, select Space Analyst.

Note: You do not need to install anything for Space Analyst to work.

Proceed to Session 2: Obtaining a Global View of Storage Using Space Analyst for IBM DB2 for Linux, Unix, and Windows
Session 2: Obtaining a Global View of Storage Using Space Analyst for IBM DB2 for Linux, Unix, and Windows

When it opens, Space Analyst shows a complete overview of the storage situation of a particular database or database server. The first tab of Space Analyst displays all pertinent global statistics regarding storage structure usage throughout a database.

There are four distinct sections displayed on the first Storage Overview tab of Space Analyst:

- Storage Overview
- Tablespace Space Overview
- Log Overview
- Tablespace Objects Overview

Space Analyst for IBM DB2 for Linux, Unix, and Windows - Storage Overview

The breakdown of space usage of the allocated tablespace space, by index, table and temp data is shown in this section. You can also see the total number of tablespaces and the number SMS and DMS spaces here.

Note: Make sure your database object statistics are up to date. Space analyst uses these statistics in the various graphs and grids.

Space Analyst for IBM DB2 for Linux, Unix, and Windows - Tablespace Space Overview

The Tablespace Space Overview section displays summary information regarding every tablespace on the database. When invoked in graph form, this section shows how much total space is allocated to each tablespace. When shown in grid form, this section shows not only the total allocated for each tablespace, but also includes information such as used space, free space, state, number of containers etc.

Tip: To see a grid-style display of the information shown in the graph, position your mouse over the graph, click the right mouse button and select the ‘toggle display’ option. To return to the graph, just perform the same actions over the grid.

When this section is in grid form, you can also perform a number of actions on a tablespace like open it in a DBArtisan editor, extract its DDL, update its object statistics and more. For example, if you want to update the statistics on all tables in a tablespace, you would perform the following:
1. Select a tablespace in a grid.

2. Right-click the tablespace, and select Update Statistics.

OR

3. On the Space Analyst toolbar click the Update Statistics.

Space Analyst for IBM DB2 for Linux, Unix, and Windows - Log Overview

The log overview provides a quick glance into database transaction log usage. This section shows the percentage of used and free log space for the database, the various database configuration parameters associated with the log space and the high watermarks for the log space usage.

Space Analyst for IBM DB2 for Linux, Unix, and Windows - Tablespace Objects Overview

The tablespace objects overview section provides an overview of how much space is used by the tables and indexes on each tablespace.

Proceed to Session 3: Identifying Storage Structure Problems
Session 3: Identifying Storage Structure Problems

Space Analyst can help you quickly find storage structure problems that threaten the availability of your databases.

Pinpointing 'out of space' Problems

You can quickly tell if your transaction logs are about to run out of free space by following these steps:

1. Open Space Analyst.
2. View the Database and Log Overview sections on the Storage Overview tab.
3. Examine the free and used space metrics in the pie chart. If the transaction log is nearing the end of free space, then action should be taken to prevent a log full error.

You can also obtain graphical views of tablespaces and pertinent storage property information by viewing the Tablespaces tab of Space Analyst. You can visually get a handle on the amount of used and free space of your tablespaces and quickly view critical storage property facts such as the number of containers for each tablespace, the space allocated for each container, the usage of tablespace space on each partition in a multi-partition database.

All the graphs can be toggled to grids by using the right mouse menu option of 'Toggle Display'. When in grid mode, very detailed information is available concerning the selected tablespace.

Note: You can perform further corrective actions on a tablespace, by opening it in the tablespace editor by using either the right mouse menu or the Command toolbar button (the yellow arrow).

Using Analysis Reports

You can run HTML-formatted reports that pinpoint all major storage-related problems for a particular database and the objects that are contained within it. To produce an Analysis Report, follow these steps:

2. If you want to change the location and report title of the report, edit the predefined entries for the Report File Name and Report Title.
3. Select the types of space problems you would like identified on the report by using the Category list.
4. Click Execute.
Space Analyst creates a frame-based Analysis report for the database you indicated.

Proceed to Session 4: Pinpointing SQL server Performance Inefficiencies

Session 4: Pinpointing SQL server Performance Inefficiencies

Space Analyst can greatly accelerate the process of locating objects in your database that are degrading overall response times because of their current inefficient storage usage.

Finding Space-related Table Problems

You can quickly tell if any tables in a tablespace that may be contributing to performance slowdowns by following these steps:

1. Open the Space Analyst and select the Tables tab.
2. Select the tablespace you would like to interrogate in the Tablespace list.
3. Click the Refresh button.

You will see a graphical count of the number of tables that are experiencing specific types of storage inefficiencies in the upper area of the tab. The table reorganization candidate details grid in the lower area of the tab can be used to view detailed storage information for every table in the selected tablespace. Space Analyst uses predefined thresholds (which you can customize by selecting the Threshold Options toolbar button) to determine how many and what tables are suffering from storage inefficiencies.

The types of table-related space problems shown in the bar graph found on the objects tab include:

- **Overflow Problems** - Overflows occur in tables when overflows occur when rows are updated with more bytes than the original row (VARCHAR fields etc.). Overflows also occurs when the new columns are added to existing tables. Since the overflow data will not be stored contiguously with the other data, it causes access inefficiencies.

- **Space Utilization Problems** - Normally, DB2 reclaims any space freed up by deletes, in subsequent insert/update operations. However, if a DB2 table has the ‘APPEND’ mode set to on and a large amount of data is deleted from the table DB2 will not reclaim freed space. Also when some types of large load operations are performed, the table may be left with a large amount of unused space.

- **Page Utilization Problems** - As the number of empty pages increases, the need for table reorganization also increases. Empty pages waste space and reduce the table scan efficiency, since empty pages are read into the buffer pool for a table scan wasting bufferpool memory.
Finding Space-related Index Problems

- Index Contention - Unless the user explicitly separates the index and table tablespaces, DB2 tables and indexes are placed on the same tablespace. This can become a bottleneck with heavily accessed tables using index scans since data and index accesses will compete for the IO device resources.

The graph at the top of the Tables tab shows the overall count of problem tables, but you can also view the details for each type of problem by using the Details grid at the bottom of the tab. For example, if Space Analyst identifies tables that have overflow records, then to find the actual tables and view details regarding the identified space problem, you would perform the following:

1. Select All from the Tablespace list in the Details grid.
2. Select All from the Table Schema list in the Details grid.
3. Select Tables with Overflow Problems from the Display list in the Details grid.
4. Click Refresh.

You would then see the actual tables that suffer from overflowed records along with their demographic details. If you wanted to take corrective action on any object, you could highlight one or more tables and click the right mouse button to bring up a menu of possible actions.

Proceed to Finding Space-related Index Problems

Finding Space-related Index Problems

You can quickly tell if any indexes in your database may be contributing to performance slowdowns by following the exact same steps as outline above for tables with one exception: You want to select the Indexes tab instead of the Tables tab. The overview graph and index details sections of the Indexes tab work in the exact same manner for indexes as they do for tables.

Proceed to Session 5: Correcting Space-related Problems
Session 5: Correcting Space-related Problems

Once you have identified space-related bottlenecks in your database with Space Analyst, you can use a number of different tools and facilities within the product to eliminate each storage headache.

Correcting Tablespace 'out of space' Problems

Space Analyst can help you quickly remedy tablespaces that are running out of room by:

- Resizing existing tablespace containers to have more room.
- Adding new containers file to an existing tablespace.
- Moving Objects from a near full tablespace to less utilized tablespace

Resizing and adding of tablespace containers can be managed by performing the following steps:

1. Open Space Analyst and select the Database Overview tab.
2. Select the graph in Tablespace Overview section and change to the grid display by selecting the right mouse menu option toggle display.
3. Select the DMS tablespace that is running low on free space and either select the Open toolbar option or the Open right mouse menu option.

This opens the Tablespace in DBArtisan’s tablespace editor. Once you are in the editor, you can remedy the tablespace problem in one of two ways:

- To resize an existing container, select the container from the grid and click the Edit button and extend/ resize the container to a new, larger size. Then close the editor and select the Alter toolbar button to make the change permanent to the tablespace.
- To add a new container to the tablespace, select the Add button in the editor, and specify the new container attributes. Once complete, close the Add Container dialog and select the Alter toolbar button to make the change permanent to the database.

Correcting Space-related Object Problems

Once you identify specific objects that need storage corrections, you can use Space Analyst to help you quickly resolve your found issues. The Space Management wizard inside of Space Analyst can be used to build reorganization and space maintenance jobs that run right the first time. All jobs can either be immediately run or scheduled for later execution.

To create a standard database or object reorganization job, follow these steps:
1. On the toolbar, click the Space Management.

2. Select New Space Management Task.

3. Click Next.

4. Select Create standard reorganization job.

5. Click Next.

6. Select the objects you would like to reorganize from the Explorer tree on the left hand side of the wizard. Note that you can reorganize full tablespaces, selected schemas or selected tables.

7. Click Next.

8. The next few panels let you customize the reorganization. You can choose to either set options at the global level (affects all objects) or specific object level. Using the options, you can reorganize tables and indexes, perform LOB and Long data reorganizations and specify other customizations.

9. The second to last panel builds your reorganization script and allows you to preview the operation.

10. Click Next.

11. The final panel allows you to execute the reorganization script immediately, or schedule it for later execution.

**Proactive Space Management**

If you have many tablespace/schemas to take care of, then you might want to relieve the burden of performing detailed storage analysis on every tablespace or schema, each of which may or may not require attention. Fortunately, Space Analyst makes it easy to create smart space management jobs that can automate this task for you.

You can create a "reorganization analyst job" that allows you to specifically select various tablespaces/ schemas or objects and then set reorganization thresholds that determine when reorganization will occur. Once constructed, you can schedule these jobs to run as often as you’d like. During execution, these jobs will interrogate your chosen database/objects and determine if a reorganization needs to occur by applying your customized reorganization thresholds. If any objects are found to need reorganization, they are dynamically reorganized using any customized options you specify. Optionally, this job can also automatically update the statistics for the selected objects before and after reorganization and rebind any packages that depend on the reorganized objects.

These "autonomic" space maintenance jobs allow you to truly "set and forget" the task of monitoring and reorganizing the space of your critical databases.
IBM DB2 fragmentation can be broken down into two basic types:

- **External Fragmentation** - this situation exists when indexes have a logical order, based on their key value, which does not match the actual physical order inside the database file that houses the index. When an ordered scan is performed on an index, I/O performance is enhanced when the physical order of the database pages matches the logical order of the index. This is because the disk head can scan in one direction instead of moving back and forth to obtain the needed information.

- **Internal Fragmentation** - this situation exists when tables and indexes aren't utilizing space as efficiently as they should. The amount of wasted space in the database pages artificially inflates the size of the table or index and causes more I/O to be performed than would otherwise be needed if the object were compacted.

Keep in mind that fragmentation is not a performance factor at all once data reaches the IBM DB2 memory caches.

Environments That Benefit From Fragmentation Elimination

One important point must be understood regarding fragmentation: not every situation benefits from fragmentation removal. Before you invest a lot of time and effort into diagnosing and attempting the removal of fragmentation, you first need to see if jumping through hoops will actually improve your database’s availability and performance.

At the highest level, the environments that benefit the most from fragmentation removal are read-intensive databases where large indexes are being frequently scanned. There are a couple of reasons why this is the case.

In most OLTP environments, data retrieval tends to be mostly selective, which negates most of the bad effects of external fragmentation. OLTP environments also often benefit from internal fragmentation because it’s smart to leave room on index pages that are being added to and updated frequently. Free index page space helps avoid the dreaded page split where a page is divided in two due to the fact that incoming clustered index data can’t logically fit on a needed page, so IBM DB2 makes room by creating two index pages out of one. Administrators oftentimes specify a low FILLFACTOR for their indexes to create internal fragmentation and hopefully avoid page splits.

Data warehousing or databases with many resource-intensive/scanning queries are another matter. These environments will likely benefit from fragmentation removal. One reason is that the indexes tend to be larger, and therefore are not cached by IBM DB2 as easily as small indexes. Remember that fragmentation has no effect on performance once the data is nestled safely in IBM DB2’s memory caches.

Another reason why these environments benefit from fragmentation removal is the effect fragmentation has on IBM DB2’s read ahead manager. The read ahead manager helps queries that perform large scans by scanning index pages (and data pages) that it believes will be read and placing them into memory before they are actually needed. Naturally, this process can reduce overall scan times because data read in memory is many times faster than when that same data must be retrieved from disk. However, fragmentation affects how well the read ahead manager works. The read ahead manager will dynamically adjust the size of I/O it performs based on the actual physical order of the data and index pages on the server. When little external fragmentation is present, the read ahead manager can work very efficiently because it can read larger blocks at a time, whereas excessive fragmentation causes the read ahead manager to read smaller blocks of data. The end result when fragmentation is present is less overall throughput.

SQL execution patterns are something else to examine. Queries that perform large index scans are the ones that should see performance improvements when fragmentation is removed in a database. In DBArtisan, you can visually set I/O statistics on in the ISQL facility and examine queries to determine the amount of physical and logical read activity. Queries that show physical and read ahead I/O may see their response times drop when fragmentation has been removed.
Diagnosing Fragmentation

If you have an environment that will benefit from reducing fragmentation, how do you go about recognizing it? There are a number of metrics and factors to consider before you can intelligently start creating reorganization plans.

When diagnosing fragmentation, pay particular attention to the following metrics:

- **Extent Fragmentation** - this highlights any gaps (lack of contiguous order) in extents and indicates the presence of external fragmentation. Percentages of 25-50% or more are not a favorable reading.

- **Logical Fragmentation** - this metric represents the percentage of pages that are out of physical order. High values (greater than 25%) for this metric may mean that index scan performance is not what it could be. Note that this statistic is meaningless for tables without clustered indexes (heap tables).

- **Average Page Density** - this metric represents the fullness of the data or index pages, and is an indicator of internal fragmentation. Remember that the more full a data or index page is, the less I/O needed by IBM DB2 when performing scans of tables or indexes. High values are good here, with anything below 50% being suspect. Low values for this metric often indicate the presence of page splitting. Keep in mind, however, that internal fragmentation isn't necessarily bad in OLTP environments where large FILLFACTORs are often specified. Also understand that small objects (those will little or no data) will likely show low readings because they simply don't consume enough space in a database page. You can ignore these objects.

- **Extent Switches** - in a perfect world, this will equal # of object extents - 1. Higher values (values many times higher than an object's extent count) can indicate external fragmentation.

- **Scan Density** - this is computed by dividing the optimum number of extent switches by the actual number of extent switches. This percentage can be misleading, however, if the object spans more than one database file and should not be considered in such an event. Values close to 100% are best.

As you can see, you can’t just blindly diagnose fragmentation in IBM DB2, but instead have to evaluate a number of factors.
"I've Reorganized, But It Didn't Help!"

Sometimes, a DBA will reorganize a table or index and no measurable benefits are noticed afterwards. The same or worse fragmentation metrics are observed for the objects in question. What could have gone wrong?

When attempting the reorganization of either tables or indexes, you have to understand that only objects that are of a significant size will show improvement from a reorganization. IBM DB2 for Linux, Unix, and Windows has stated that objects with less than 1,000 pages will oftentimes offer no performance improvements whatsoever from being reorganized.

Other points to keep in mind include:

- Tables without indexes receive zero benefit (naturally) from running either a DBCC DBREINDEX or a DBCC INDEXDEFRAG. The only way to reorganize a table without indexes is to create a clustered index on the table and then immediately drop it.

- Heap tables should not be diagnosed as having fragmentation through the logical scan fragmentation measure. This metric is meaningless for such tables.

- As mentioned above, small objects seldom benefit from reorganizations. For example, the page density for a table with only 10 rows in it will likely not be high, and reorganizing it won’t change things one bit. You need to keep such things in mind when determining whether to reorganize an object or not. Space Analyst keeps you informed of not only reorganization metrics but object metrics (extent size, row counts, etc.) as well so you can make smart reorganization choices.

- Lack of contiguous free space can result in all fragmentation not being eliminated. Without large amounts of contiguous free space, reorganization operations may have to reuse other areas of space within the database files. The end result is oftentimes an index being reorganized, but still having an amount of logical scan fragmentation.
Forwarded Rows

IBM DB2 will move rows in a table under certain conditions. One situation might arise when you update a row in a table that has a variable-length column to a larger size that will no longer fit on its original page. Another situation would be if IBM DB2 moves a row when the clustered index column changes. When IBM DB2 creates a forwarding pointer, the pointer remains in place unless one of two things happens. The first is when a row shrinks enough to move back to its original location. The second is when the entire database shrinks. When a database file shrinks, IBM DB2 will reassign the row identifiers, which are used as the row locators, so the shrink process never generates forwarded rows.

Forwarded records can reduce performance at times because additional I/O is involved to first obtain the record pointer to the relocated row, and then the row itself. But when does row forwarding become a problem? For example, just because a table has one hundred forwarded rows, does that mean a performance problem exists? The answer is: it depends. If the table has one hundred rows in it, then yes, a problem exists - 100% of the table suffers from forwarded rows. If the table has three million rows, then the forwarded row situation is likely not causing much fuss in the database.
Parameters, Arguments, Options, and Variables Appendix

This appendix provides nothing more than a listing of the server initialization parameters, servers and options supported by DBArtisan.

Note: It is beyond the scope of this document to provide detailed documentation on the parameters and options listed. Refer to the documentation set of the relevant DBMS platform for details. For guidance, see Accessing Third Party Documentation.

See the following topics for listings:

- Supported DB2 LUW System Configuration Parameters
- Supported MySQL Server System Variables
- Supported Oracle Initialization Parameters
- Supported SQL Server Configuration Options
- Supported Sybase ASE Configuration Parameters
- Supported Sybase IQ Configuration Parameters
- Data Pump Import/Export Parameters that can be Added Manually

Supported DB2 LUW System Configuration Parameters

The following parameters are available from the Explorer’s Database Configuration node. For information on working with these parameters, see Working with Configuration/initialization Parameters.

Data Pump Import/Export Parameters that can be Added Manually

Pages of the Data Pump Import/Export Wizards let you provide a minimal set of `impdp.exe` and `expdp.exe` parameter values. The Advanced Parameters tabs let you provide additional name=value pairs. The following table lists the parameters available on that page.

<table>
<thead>
<tr>
<th>DATA_OPTIONS</th>
<th>ENCRYPTION_PASSWORD</th>
<th>ESTIMATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXCLUDE</td>
<td>FLASHBACK_SCN</td>
<td>FLASHBACK_TIME</td>
